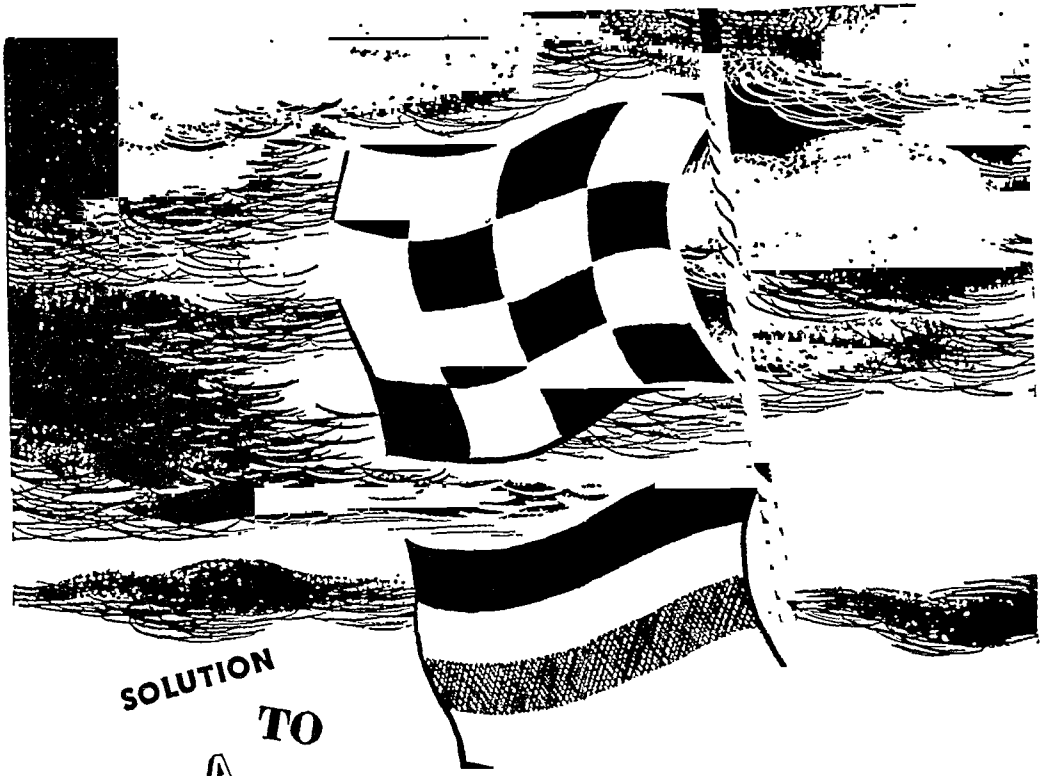
NASAL CONGESTION

ngested nasal passages are troubling to both
: patient and his physican. Each seeks a safe
pendable mode of relief.



'Vaporole' Ephedrine Isotonic Solution
(queous) clears nasal passages without mu-
sal irritation. Because it is physiologically
sible and contains no irritating antiseptics,
ciliary function is unimpaired, vaso-constriction
is immediate and prolonged, there is no aggrava-
tion of after-congestion.

'Vaporole' Ephedrine is pleasantly aromatic and has a non-oily vehicle—features of particular importance in the treatment of children. Bottles of 1 fluid ounce and 1 pint.

Vaporole' Ephedrine Isotonic Solution (aqueous)

containing 1 per cent ephedrine in an isotonic solution of sodium, potassium and calcium chlorides and dextrose (modified Locke's solution).

JRROUGHS WELLCOME & CO. (U.S.A.) INC., 9-11 East 41st Street, New York 17, N. Y.

SOLUTION TO A *familiar*

DISTRESS SIGNAL

When the patient complains of "indigestion," it may point to any of a multitude of underlying disturbances among which functional or pathologic changes at any level of the biliary tract are of high incidence as is pancreatic deficiency.

In most of such cases, *Depancol* has proved its efficacy. A protective enteric coating assures its effects which are:

1 CHOLERETIC—*by increased flow of physiologically normal bile.*

2 DIGESTIVE—*by action of bile salts and the pancreatic enzymes supplied.*

Depancol contains no laxative or cathartic drugs. Your pharmacy may obtain the enteric coated *Depancol* in bottles of 50, 500 and 5000.

THE Maltine COMPANY

Fulfillment of a Protected Pregnancy

Neither hopeless nor helpless are cases of threatened or habitual abortion due to corpus luteum deficiency. Such pregnancies can be protected, in many cases, by decisive, early treatment with PROLUTON* (progesterone for intramuscular injection) or PRANONE* (anhydrohydroxy-progesterone for oral administration) which reduce the contractility of the myometrium.

In habitual abortion 5 to 10 mg. of Pranone are given *orally* daily, increasing to 30 or 40 mg. daily during times of greater requirement, or 5 mg. of Proluton three times weekly may be *injected*. Therapy is continued until quickening occurs.

In threatened abortion injections of 5 to 10 mg. of Proluton are given daily until bleeding and pain are completely controlled. Subsequent treatment may be given as for habitual abortion.

OCTOFOLLIN

has been the name employed to designate the brand of

BENZESTROL

marketed by Schieffelin & Co. Benzestrol has been recognized as the generic name for 2, 4-di(p-hydroxyphenyl)-3-ethyl hexane by the Council on Pharmacy and Chemistry of the American Medical Association. It has been decided to discontinue the use of the name Octofollin and hereafter the product will be known and labelled Schieffelin Benzestrol

Schieffelin
BENZESTROL

This fine synthetic estrogen is supplied in the same strengths and sizes as formerly, namely

BENZESTROL *Tablets:*
0.5, 1.0, 2.0, 5.0 mg. Bottles 50, 100 and 1,000.

BENZESTROL *Solution:*
5.0 mg. per cc, in 10cc rubber capped, multiple dose vials.

BENZESTROL *Vaginal Tablets:*
0.5 mg. bottles of 100.

Schieffelin & Co.

IN THE TREATMENT OF

Industrial Contact Dermatoses

High Therapeutic Efficacy—TARBONIS is anti-inflammatory, is decongestant, and promotes resolution. It is of proven value in the control of industrial dermatoses (against a wide range of irritants), eczema, psoriasis, seborrheic dermatitis, certain tinea infestations, lichen simplex chronicus—in fact, whenever tar is indicated.

A Dependable Antipruritic—TARBONIS relieves the pruritus attending many skin conditions—stops scratching.

An Effective Barrier—Wide use in industry has demonstrated the protective efficacy of TARBONIS against skin irritants of almost every conceivable nature, and under exposure to all kinds of ordinarily disturbing physical conditions—excessive heat, dryness, steam, etc.

TARBONIS, a unique tar ointment, presents all the therapeutic efficacy of crude tar in a new, highly cosmetic form. Its active ingredient is a liquor carbonis detergens (5%), made by a process distinctly its own.

The therapeutic efficacy of tar is attributed to its complex contents of phenol and cresol derivatives, its sulfur compounds, its unsaturated hydrocarbons. In the liquor carbonis detergens of TARBONIS these compounds are present in notably higher concentrations.

The vehicle of TARBONIS is a special vanishing-type cream which contributes to the therapeutic superiority of TARBONIS by exhibiting *all* the contained active substance to the area to which applied.

Physicians are invited to send for clinical test sample and comprehensive, illustrated brochure on tar therapy.

THE TARBONIS COMPANY

FIGHT INFANTILE PARALYSIS

This plea keynotes the great humanitarian struggle waged unceasingly by the National Foundation for Infantile Paralysis since its inception in 1938 . . . and climaxed each January by an intense public awareness and support campaign.

The vast scope of the battle against infantile paralysis — involving the time, skill and knowledge of our finest doctors and scientists — cannot be comprehended by the majority of people. However, so deep is the desire of Americans to see the obliteration of this dread disease, that they have to date contributed millions of dollars through annual March of Dimes appeals for research purposes alone.

In recognition of the importance of the work of the National Foundation, Rexall Drug Stores are proud to join with the American people in support of the 1945 March of Dimes, January 14–31.

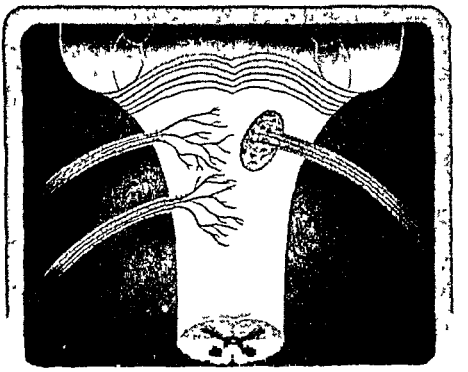
TO THE DOCTOR . . .

fighting a persistent hemoglobin reduction

LIVER
IRON
VITAMINS
B_1-B_2-B_6-C

Containing in each capsule 3½ grs. liver concentrate, 2 grs. ferrous sulfate, 10 mg. Nicotinamide, 2 mg. Vitamin B_1, 2 mg. Vitamin B_2, 30 mg. Vitamin C (ascorbic acid), Vitiliver offers several advantageous features:

(a) Components of Vitamin B Complex are involved in hematopoiesis. (1)



(b) Vitamin C administered with iron aids in its absorption. (2)

(d) The addition of liver to iron in secondary anemia has secured a more rapid hemoglobin regeneration than when either was given alone. (3)

Vitiliver is well tolerated and adapted to protracted dosage. The small capsules are easily swallowed or may be emptied into beverages, as Vitiliver will not impair flavor. Send for clinical sample to Myron L. Walker Company, Inc., Mount Vernon, N. Y.

Metamucil softens the fecal residue, protects intestinal mucosa and exerts a gentle, stimulating, physiologic peristalsis.

Metamucil is the highly refined, non-irritating extract of a seed of the psyllium group, Plantago ovata (50%), combined with dextrose (50%).

Metamucil mixes readily with liquids—is pleasantly palatable. Supplied in 1-lb , 8-oz , and 4-oz. containers.

G. D. Searle & Co , Chicago 80, Illinois.

Metamucil is the registered trademark of G D Searle & Co.

SEARLE

These published results apply only to ERTRON

"...improvement was sustained in the majority of cases..."

"...beneficial effects are sustained and may be permanent even after therapy has stopped..."

"...improvement was manifested by decreased pain, greater mobility, reduction of deformity, and improved muscular tone..."

Ten years of continuous research covering thousands of cases in leading arthritis clinics, universities and large accredited hospitals have produced an important compilation of evidence emphasizing the efficacy and safety of ERTRON in the treatment of arthritis.

These clinical studies were based on the use of ERTRON—consequently the results reported apply only to ERTRON.

Maximum beneficial effects are produced when all antiarthritic measures indicated are utilized for a particular patient. These include medical, nutritional and orthopedic therapy.

ERTRON alone—and no other product—contains electrically activated, vaporized ergosterol (Whittier Process).

ERTRON Parenteral For the physician who wishes to supplement the routine oral administration of ERTRON by parenteral injections, ERTRON Parenteral is available in packages of six 1cc. ampules. Each ampule contains 500,000 U.S.P. units of electrically activated, vaporized ergosterol (Whittier Process).

ERTRONIZE THE ARTHRITIC

ERTRONIZE MEANS: Employ ERTRON* in an adequate daily dosage over a sufficiently long period to produce optimal results. Gradually increase the dosage to that recommended or to the toleration level. Maintain this dosage until maximum improvement occurs.

Supplied in bottles of 50, 100 and 500 capsules.

Ethically Promoted

White's

Sulfathiazole

Gum

THE rationale of this most effective new local sulfonamide treatment lies in this:

Even a single tablet produces, throughout the entire oropharyngeal area—for as long as one hour's chewing—a con-

FOR THE MORE EFFECTIVE)CAL SULFONAMIDE TREATMENT OROPHARYNGEAL INFECTIONS

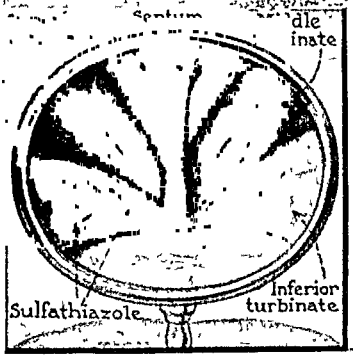
centration of *locally active* sulfathiazole, dissolved in saliva, averaging 70 mg. per cent. Yet even with *maximal* dosage over a prolonged time-period—and even in children—blood levels produced are so low as to be immeasurable for the most part, and only rarely even approach 1 mg. per cent.

Local efficacy, and freedom from systemic toxicity, have been proved in wide clinical experience to be as impressive as the striking figures cited above would suggest.

White's Sulfathiazole Gum is supplied in packages of 24 sanitaped tablets in slip-sleeve prescription boxes—*on prescription only.*

WHITE LABORATORIES, INC. PHARMACEUTICAL NEWARK 7, N. J.

Paredrine-Sulfathiazole



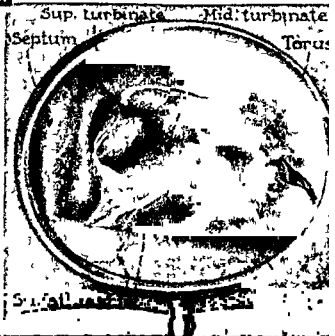
How It Shortens the Course of Infection and Helps Avert Sequelae to Colds

THESE drawings—from photographs presented as a scientific exhibit at the 1944 Meeting of the American Academy of Ophthalmology and Otolaryngology—demonstrate why Paredrine-Sulfathiazole Suspension is so strikingly effective in nasal and sinus infections. The choanae of patient T. D.—with subacute pansinusitis—are illustrated.

The dramatic success of Paredrine-Sulfathiazole Suspension in aborting colds and averting complications is largely due to its prolonged bacteriostatic action. When the Suspension is administered on retiring, for example, sulfathiazole can often be observed on infected mucosa the next morning—conclusive evidence that bacteriostasis has persisted all night long.

The fundamental reason for this prolonged bacteriostatic action is the fact that Paredrine-Sulfathiazole Suspension—not a solution, but *a suspension* of free sulfathiazole—covers the nasal mucosa with a fine, even frosting of sulfathiazole, which does not quickly wash away. Yet the Suspension does not cake or clump, and does not interfere with normal ciliary action.

Suspension—



30 MINUTES AFTER INSTILLATIO

The Suspension has been swept onto infected areas, where ciliary action is impaired. The sulfathiazole remain on infected areas and keeps producing a bacteriostatic solution.

45 MINUTES AFTER INSTILLATION

Sulfathiazole mixed with pus is passing over the orifice of the Eustachian tube. Should pus enter the middle ear, the sulfathiazole will minimize the likelihood of otitis media

50 MINUTES AFTER INSTILLATION

A NEW, DIFFERENT AND BETTER FORM OF SULPHUR FOR

ACNE VULGARIS

COLLO-SUL CREAM contains active, stable colloidal sulphur in a water-miscible, emulsion-base cream. It gives excellent sulphur action without irritation—is free from any objectionable "sulphur" odor and annoying greasiness.

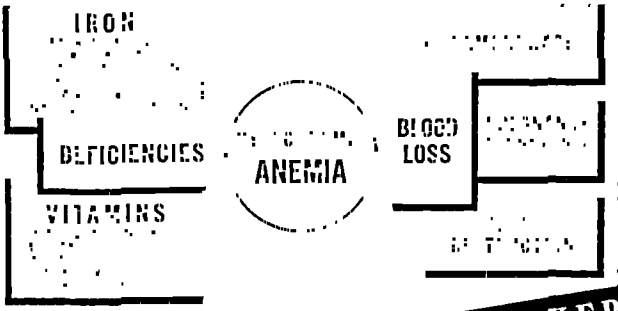
IODINE...

Its Action in Antisepsis



The germicidal action of Iodine is not limited to the vegetative bacilli. It destroys certain spore-bearing organisms as well. In numerous tests comparing Iodine with other antiseptics, the toxicity index of Iodine has been found to be low.

The germicidal value of Iodine has been so effectively demonstrated, both clinically and in laboratory tests, that Iodine is usually a standard against which other antiseptics—old or new—are compared.

The physician may rely upon Iodine in pre-operative skin disinfection and in the treatment of wounds.

FOR THE INDUSTRIAL WORKER

The worker cannot be expected to deliver quality products if his tools are in impaired condition. Neither can he achieve maximum production if his physical status is below par.

Secondary anemia, encountered with increasing frequency among industrial workers, makes for easy fatigability, reduces efficiency, and—by lessening acuity—*contributes to accidents. Correction of anemia thus is a major concern in industrial practice.*

Heptuna provides all essential factors needed to restore not only the blood picture but the patient as well. Since this anemia usually is the result of multiple nutritional deficiencies, Heptuna proves particularly applicable.

In addition to an adequate amount of highly available iron it provides the fat-soluble vitamins A and D, and the B-complex vitamins (partly derived from liver extract and yeast) essential to iron utilization, better appetite, and improved endurance. In most instances *one capsule of Heptuna per day together* with the daily diet proves adequate in correcting the anemia.

FOOTWEAR

SHOES AS THERAPEUTIC AGENTS

No doctor can ignore that shoe therapy is a major factor in the treatment of many foot disorders. In some cases, however, when further medical or surgical treatment is required, the shoes must be adjusted to conform to any changes such treatments make in the shape or size of the feet.

Pediforme shoes are prepared through experienced craftsmen to make the necessary adjustments as prescribed by the orthopedic surgeon or physician in these cases.

With purchases restricted it is readily apparent that substantial shoes, capable of reconstruction or easy adjustment, should be prescribed. For all practical purposes, Pediforme footwear may well be considered in shoe therapy.

A SHOE FOR EVERY MEMBER OF THE FAMILY . . . A SHOE FOR EVERY INDIVIDUAL REQUIREMENT.

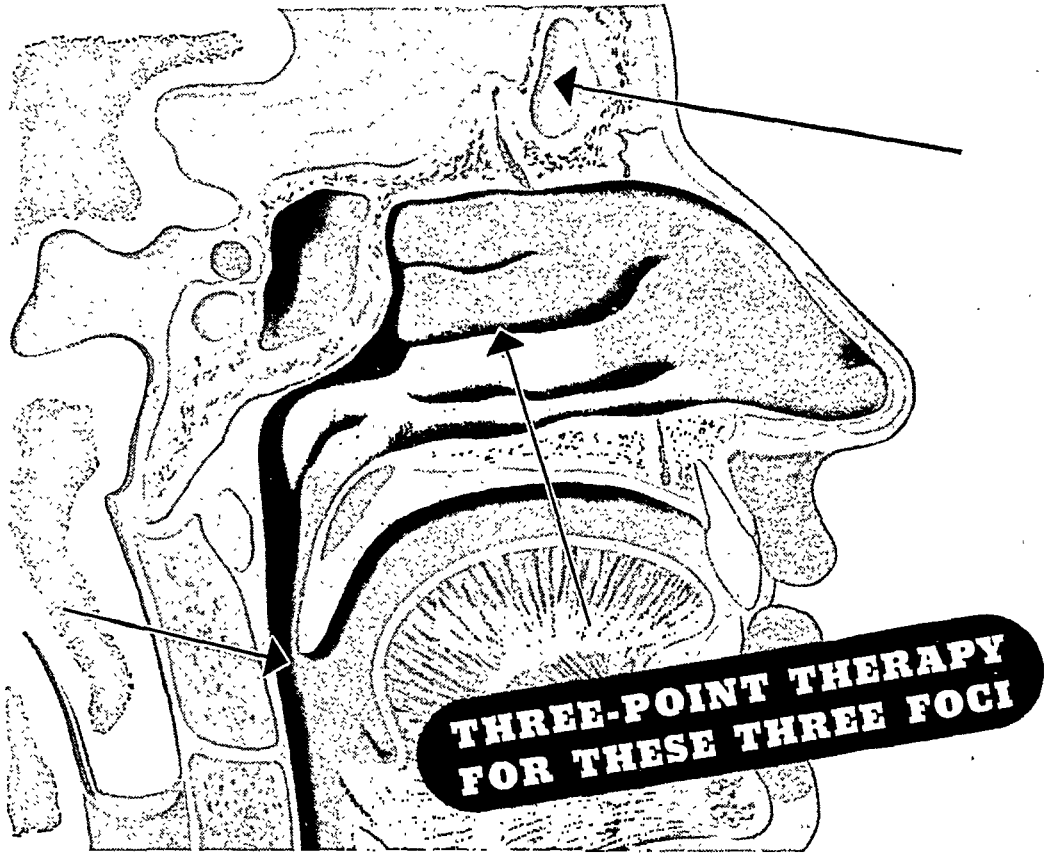
Heinz Now Offers a Complete Line of Baby Foods IN GLASS!

High-Quality Heinz Strained And Junior Foods Provide Tempting, Well-Balanced Meals For The Babies And Toddlers In Your Care

Meats—Among the delicious, scientifically prepared Heinz Strained Foods for infants are nutritious Beef Broth with Beef and Barley, Beef and Liver Soup, and choice Vegetables with Lamb. Two special Heinz Junior Foods—Chicken-Farina-Vegetable Porridge and Lamb and Liver Stew—furnish important protein values for older babies.



Fruits—A well-balanced fruit-and-cereal combination, Heinz Strained Apricots and Oatmeal is a dish small babies enjoy. Heinz Strained Prunes, Peaches, savory Pears and Pineapple, and Applesauce, are bland, enticing fruits—not too sweet, not too tart.

Vegetables—Heinz makes Strained Beets, Carrots, Green Beans, Spinach, Peas, Tomato Soup and Vegetable Soup for babies. These specially grown vegetables are scientifically cooked and vacuum-packed to retain a high degree of minerals and vitamins . . . For older babies, Heinz prepares Creamed Tomatoes and Rice, Creamed Green Vegetables, Chopped Green Beans, Chopped Spinach and Chopped Mixed Vegetables.

Desserts—Creamy Heinz Strained Custard and Apple Prune Pudding are light, energy-giving, easy for infants to digest. Pineapple Rice Pudding and Prune Pudding—both highly nutritive Junior Foods—are two desserts you'll want to recommend for toddlers!

IN the treatment of paranasal infection, ARGYROL offers more than effective antisepsis, decongestion without vasoconstriction, and cleansing effect. It also provides for stimulation, *synergetically*, of the membrane's inherent, natural defense mechanism.

Treatment with ARGYROL is wisely directed to these three foci of paranasal infection:

1. the nasal meatus . . . by 20 per cent ARGYROL instillations through the naso-lacrimal duct.
2. the nasal cavities...with 10 per cent ARGYROL solution in drops or by nasal tamponage.
3. the fauces and pharynx . . . by swabbing with 20 per cent ARGYROL solution.

How Argyrol Acts on the Membrane

DECONGESTIVE—ARGYROL'S decongestive effect on the membrane is the result of its demulcent, osmotic action. The withdrawal of ARGYROL tampons from the post-nasal cavities frequently brings forth a long ropy mucous discharge measuring as much as two feet or more.

BACTERIOSTATIC—Although proved to be definitely bacteriostatic, ARGYROL is non-toxic to tissue. In nearly half a century of wide medical use of ARGYROL, no case of toxicity, irritation, injury to cilia or pulmonary complication in human beings has ever been reported.

STIMULATING—Soothing to nerve ends in the membrane and stimulating to glands, ARGYROL'S action is more than surface action. For it acts *synergetically* with the membrane's own tissue defense mechanism.

When you order or prescribe ARGYROL, make sure you specify Original Package ARGYROL.

ARGYROL *THE PHYSIOLOGIC ANTISEPTIC WITH SYNERGETIC ACTION . . .*

THE FETUS, THE MOTHER and PROTEIN—

Numerous medical reports continue to stress the importance of adequate protein in the diet of the pregnant woman.

Recently Burke* and her associates have shown the importance of protein intake in the mother's diet during pregnancy, concluding that "from this study it would appear that from the standpoint of birth length, birth weight and general physical well-being of the infant at birth, the diet should be liberally supplied with protein during pregnancy."

To encourage the necessary increased intake of easily assimilable protein without the burden of excessive solid food, discerning clinicians suggest—

HORLICK'S

Whether prepared with milk or water, Horlick's offers a palatable means of augmenting the supply of protein in the diet.

9 out of 10 cases of EPILEPSY are treated in the home

Of the more than a half-million persons in the United States who suffer from epilepsy, only about 50,000 are in public institutions.[1] Thus, about 90 per cent of the therapy of this disease rests on the shoulders of the physician in private practice.

Management of the epileptic in the home demands the use of therapeutic measures which will control seizures effectively, and favorably influence such psychological factors as make for better adjustment of the patient to family life, as well as to his association with others. The objective of the physician is to make it possible for the epileptic, adult or child, to live a normal life with his family.

Dilantin Sodium is a superior anticonvulsant that is relatively free from hypnotic action. It is effective in many cases which fail to respond to bromides or barbiturates. With dosage skilfully adjusted by the physician to the requirements of the individual patient, it provides complete control over seizures in a substantial percentage of cases. In others it lengthens the interval and diminishes the effect of the seizures.

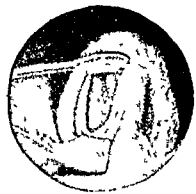
BELBARB

AN *Excellent* SEDATIVE *and* HYPNOTIC

The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg, Arch. f. exp. P. & P. CLX, 276) renders possible attainment of desired effects with relatively small doses, thus avoiding "hang over" and other unpleasant side-actions. In contrast to galenical preparations of belladonna, such as the tincture, Belbarb *has always the same proportion of the alkaloids.*

Indications: Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

Formula: Each tablet contains ¼ grain phenobarbital and the three chief alkaloids, equivalent approximately to 8 minims of tincture of belladonna.



Belbarb No. 2 has the same alkaloidal content but ½ grain phenobarbital per tablet.

CHARLES C. HASKELL & CO., INC., RICHMOND, VIRGINIA

A better means of nasal medication

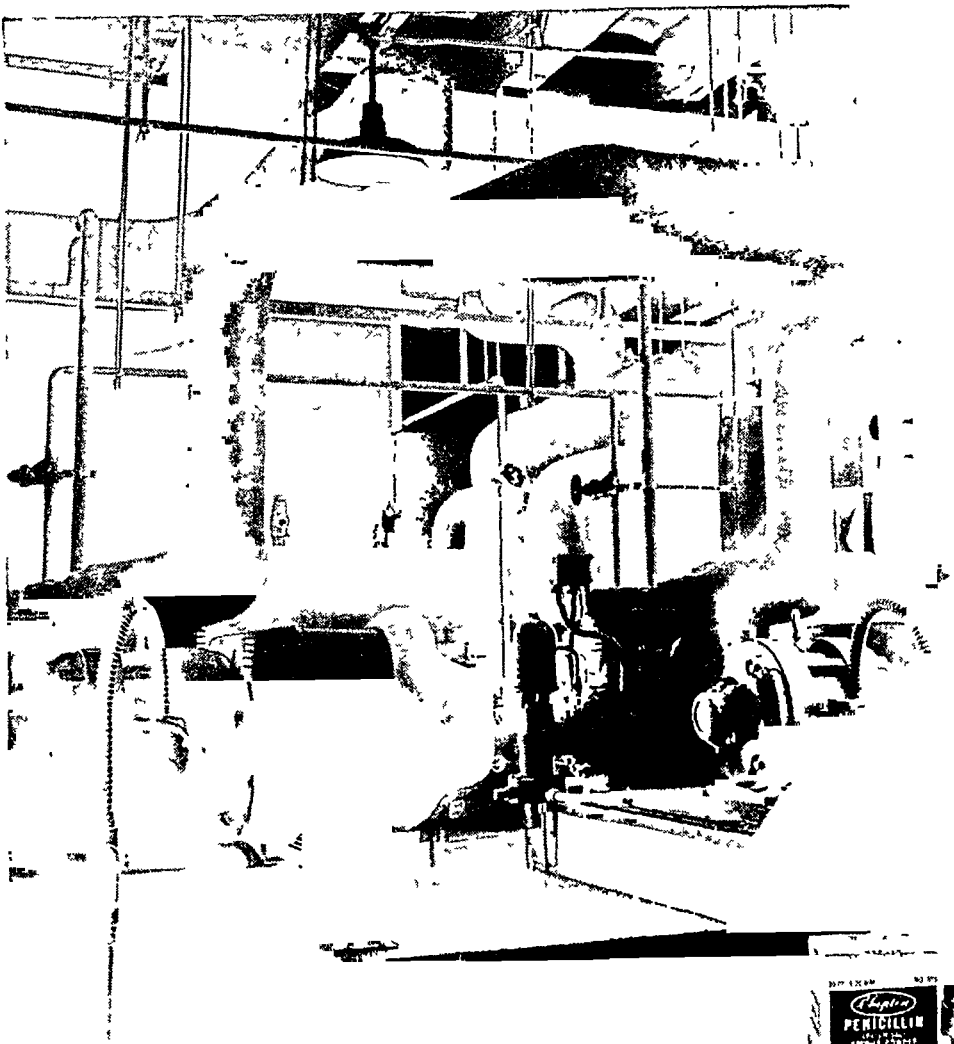
BEFORE TREATMENT

Inferior and middle turbinates are highly engorged and in contact with the septum. The airway is completely blocked.

9 MINUTES AFTER TREATMENT

Maximum shrinkage has been obtained with 2 inhalations from Benzedrine Inhaler. The turbinates are contracted *The airway is open.*

Butler and Ivy state that—for administering vasoconstrictive drugs—inhalers and sprays are preferable to nasal drops, and are—in most cases—"the better means of nasal medication," because: (1) ". . . the drug reaches the nasal mucosa in more diffuse form . . ."; (2) " . . . the mucosa is never severely ischemic at any one point, but the effect is spread throughout the nasal cavity . . ."; (3) even when prolonged medication is required, there is ". . . far less pathologic change than that resulting from the use of nasal drops."



Arch Otolaryng., 39 109 123, 1944.

Each Benzedrine Inhaler is packed with racemic amphetamine, S. K. F., 200 mg.; oil of lavender, 60 mg., and menthol, 10 mg.

Background Counts

AMNIOTIN has now been available for your use for more than sixteen years. Since 1928. this dependable estrogen has been continuously subject to that most critical of all tests—clinical usage.

More recently. a number of other estrogens have been introduced. Much ink has been spilled on the question of their relative merits. economy and potency and the units in which that potency is expressed.

Amniotin, at the end of sixteen years, still stands high in terms of dependability, clinical effectiveness, freedom from side-effects and economy. For the case requiring either massive or minimal dosage. Amniotin is available in a form and potency which makes it possible to administer that dose conveniently and economically.

Today as in 1928, Amniotin, by all practical criteria, possesses the desirable qualities you look for in an estrogen. It provides you with a potent, natural estrogen. economical. convenient. and standardized in the universally accepted International Unit. No other estrogen has given more consistent satisfaction over a longer period.

Amniotin is one of many fruits of the eighty-six years devoted by the Squibb Laboratories to the translating of experimental research into practical reality. Could any estrogen have a better background?

For a reliable, potent, economical estrogen, ask your pharmacist for

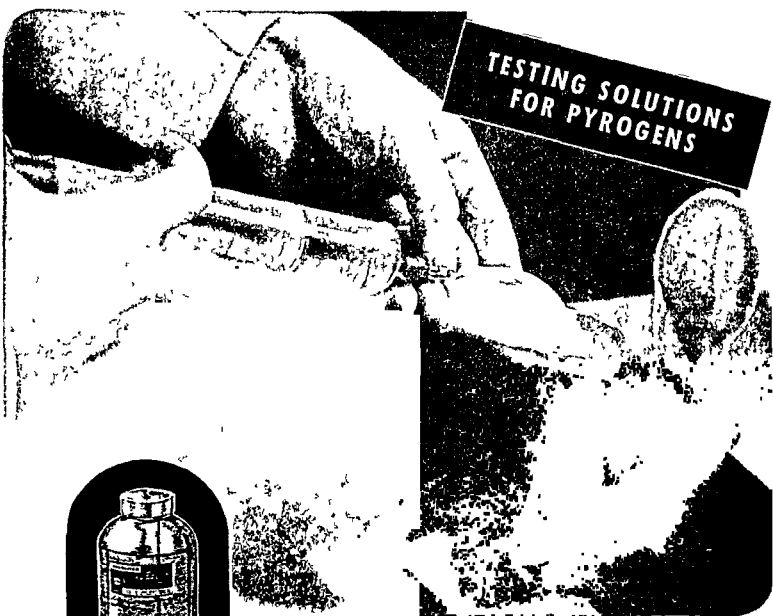
physiologist in studying body processes and body requirements.

It was originally thought that the nutritious properties of food were due to the presence of a single substance which was referred to under the term "aliment." In 1834 Prout[1] stated that there were three great "staminal or proximate principles"—a saccharine principle, an oily principle, and an albuminous principle, which provided the essential nutritive constituents of all organized bodies. It was considerably later that the need for mineral elements was established, followed in the present century by the discovery of the first vitamin. Now it appears that nearly forty distinct chemical substances are required in the diet.

Originally it was thought that the nitrogenous compounds of the body were built up from nitrogen in the air. But in 1816 François Magendie,[2] the great French physiologist who became the teacher of Claude Bernard, reported his experiments showing that animals cannot live on sugar alone or starch alone, and that nitrogenous substances were required in the diet. The term "protein" was coined some fifteen years later. Then observations commenced to accumulate which were the forerunner of the recognition that not all proteins are of equal value in the diet, and of the modern, amino-acid concept of protein metabolism. In his famous "gelatin report" published in 1841, Magendie showed that gelatin did not take the place of meat protein. Thirty-five years later Escher,[3] a practicing physician, running an experiment with dogs, reported that the deficiency of gelatin could be made good by the addition of tyrosine. This experiment was published in an obscure journal, and it gained little attention at the time. Then, early in the twentieth century, came the work of Osborne and Mendel,[4] clearly showing that certain proteins which resulted in nutritive failure could be rendered satisfactory by the addition of missing amino acids. The brilliant work of the last fifteen years, notably by Rose and his associates,[5] which has made use, experimentally, of mixtures of amino acids in place of any protein in the diet, has given us our modern knowledge of "protein quality."

The first knowledge of mineral nutrition could be considered to have begun with the recognition of the need for common salt. Then came the studies of bones which established the need for calcium and phosphorus.



The development of this knowledge was greatly stimulated by observations that grazing animals developed weak and easily broken bones on pastures very low in phosphorus. The studies which have resulted in establishing the quantitative requirements for the various minerals have taken place primarily in the present century. They have been made possible by the concurrent developments in the vitamin field which have enabled workers to use purified diets complete in all other constituents. While the need for all of them has not yet been established in human experiments, it appears that at least thirteen mineral elements are essential for the normal functioning of the body.

The development in the field of vitamins is, of course, the most recent. Magendie really made the first observation in 1816 when, in using diets consisting of sugar alone or fat alone, he described an eye trouble which was undoubtedly xerophthalmia. While the occurrence of such diseases as scurvy was recognized centuries earlier and cured by appropriate dietary additions, a large amount of physiologic and nutritional knowledge had to accumulate before these deficiencies could be produced experimentally and their specific nutritional causes be established. Thus, the recognition of the existence of the first vitamin, namely, "fat-soluble A," was not made until 1913[6,7] and its chemical identification did not occur until years later. During the past ten years, particularly, advances in the field have been extremely rapid and there now appear to be more than a dozen compounds, definitely identified chemically, which are entitled to be called "vitamins." The significance of some of them in the case of man, and particularly the question of their quantitative need in the diet, remain unsettled.

Beginning in the middle of the last century, the concept was developed for farm animals that the nutritional needs could be determined with reference to age, size, and activity, and expressed in terms of the nutrients found by conventional food anal-

The Facts About Nutrition

It has been inferred that physicians are somewhat skeptical of nutritional studies.* This cannot be denied. Too many popular reports of this subject contain exaggerated or inaccurate statements. These statements are undoubtedly responsible, at least in part, for the skepticism which marks the clinician's attitude. The war, of necessity, has raised the question of food nutritional values. Many scientists who have labored with the noblest of purpose on serious nutritional problems have gone unheard because of the overwhelming voice of those lamenting deficiencies in our diet and the consequent casualties among the American people. Can there be a physician who has not wondered how the human race survived to 1913, the date when the first vitamin was discovered?

There have been attempts in recent years to appraise the nutritional status of individuals by laboratory and special instrument methods. Physicians followed this program with the highest hopes. Then, one after another, the exalted experiments or easy signs of nutritional deficiencies fell short. At first, the adaptometer, and then the biomicroscope, seemed the answer for the diagnosis of vitamin A deficiency. Hundreds of investigators have argued the plasma ascorbic acid level that is optimum for health. Corneal vascularization, formerly thought to be strictly an indication of riboflavin deficiency, has now been observed in several other conditions. Hence, it cannot by itself be accepted as specific.

In order to clarify the clinician's thinking and free him from skepticism, he must be shown through his own observations on human beings rather than by claims of the experts. To use efficiently [illegible] sician must be far [illegible] is JOURNAL has pre[illegible] sity, several editorials on the background and modern conception of nutrition principles for normal people with which every physician should be familiar.

The first installment appears below.

Milestones in Nutrition

The great French chemist, Lavoisier, is frequently referred to as the founder of the science of nutrition. He established the chemical basis of nutrition in his famous respiratory experiments, carried out before the French Revolution. His studies led him to state, "La vie est une fonction chimique." Thus, chemistry became a tool used by the

* Bessey, O. A.: Proceedings, Research Conference on the Relation of Nutrition to Public Health, Oct. 11, 1943, p. 23.

physiologist in studying body processes and body requirements.

It was originally thought that the nutritious properties of food were due to the presence of a single substance which was referred to under the term "aliment." In 1834 Prout[1] stated that there were three great "staminal or proximate principles"—a saccharine principle, an oily principle, and an albuminous principle, which provided the essential nutritive constituents of all organized bodies. It was considerably later that the need for mineral elements was established, followed in the present century by the discovery of the first vitamin. Now it appears that nearly forty distinct chemical substances are required in the diet.

Originally it was thought that the nitrogenous compounds of the body were built up from nitrogen in the air. But in 1816 François Magendie,[2] the great French physiologist who became the teacher of Claude Bernard, reported his experiments showing that animals cannot live on sugar alone or starch alone, and that nitrogenous substances were required in the diet. The term "protein" was coined some fifteen years later. Then observations commenced to accumulate which were the forerunner of the recognition that not all proteins are of equal value in the diet, and of the modern, amino-acid concept of protein metabolism. In his famous "gelatin report" published in 1841, Magendie showed that gelatin did not take the place of meat protein. Thirty-five years later Escher,[3] a practicing physician, running an experiment with dogs, reported that the deficiency of gelatin could be made good by the addition of tyrosine. This experiment was published in an obscure journal, and it gained little attention at the time. Then, early in the twentieth century, came the work of Osborne and Mendel,[4] clearly showing that certain proteins which resulted in nutritive failure could be rendered satisfactory by the addition of missing amino acids. The brilliant work of the last fifteen years, notably by Rose and his associates,[5] which has made use, experimentally, of mixtures of amino acids in place of any protein in the diet, has given us our modern knowledge of "protein quality."

The first knowledge of mineral nutrition could be considered to have begun with the recognition of the need for common salt. Then came the studies of bones which established the need for calcium and phosphorus.

The development of this knowledge was greatly stimulated by observations that grazing animals developed weak and easily broken bones on pastures very low in phosphorus. The studies which have resulted in establishing the quantitative requirements for the various minerals have taken place primarily in the present century. They have been made possible by the concurrent developments in the vitamin field which have enabled workers to use purified diets complete in all other constituents. While the need for all of them has not yet been established in human experiments, it appears that at least thirteen mineral elements are essential for the normal functioning of the body.

The development in the field of vitamins is, of course, the most recent. Magendie really made the first observation in 1816 when, in using diets consisting of sugar alone or fat alone, he described an eye trouble which was undoubtedly xerophthalmia. While the occurrence of such diseases as scurvy was recognized centuries earlier and cured by appropriate dietary additions, a large amount of physiologic and nutritional knowledge had to accumulate before these deficiencies could be produced experimentally and their specific nutritional causes be established. Thus, the recognition of the existence of the first vitamin, namely, "fat-soluble A," was not made until 1913[6,7] and its chemical identification did not occur until years later. During the past ten years, particularly, advances in the field have been extremely rapid and there now appear to be more than a dozen compounds, definitely identified chemically, which are entitled to be called "vitamins." The significance of some of them in the case of man, and particularly the question of their quantitative need in the diet, remain unsettled.

Beginning in the middle of the last century, the concept was developed for farm animals that the nutritional needs could be determined with reference to age, size, and activity, and expressed in terms of the nutrients found by conventional food anal-

yses. This idea was carried over to human nutrition in the development of dietary standards. In this development, Atwater[5] was the pioneer in this country (working period 1890–1910). He worked out the calorie needs of man and evaluated foods in terms of the calories useful to the body. But he dealt only with calories and protein. The modern dietary standards take account of minerals and vitamins as well. Here much needs to be learned, particularly as regards vitamin requirements.

Our New Executive Officer

The Medical Society of the State of New York is indeed fortunate in being able to acquire the services of Dr. Robert Roger Hannon, Ph.C., B.S., our distinguished new Executive Officer. He will represent the Society with the old upstate office at 100 State Street, Albany, as his headquarters, the office until recently presided over so constructively, competently, and graciously by Dr. Joseph S. Lawrence, now of Washington, D.C.

Dr. Hannon was born in Amsterdam, New York, but attended grammar school and the University Military School at Mobile, Alabama. He then took his academic work at the University of Washington, in Seattle, where he received the degrees of Pharmaceutical Chemist and Bachelor of Science in 1915.

He graduated in medicine from Johns Hopkins Medical School, Baltimore, in 1919, interned at Ancon Hospital, Ancon, C.Z., 1919–1920, where he studied tropical disease particularly. He then returned as a Fellow in medical research to Johns Hopkins, 1920–1921, and also as instructor in medicine. In the following years he was resident and instructor in medicine at Cornell Medical School, New York City, and assistant adjunct visiting physician at Bellevue Hospital in 1924. In 1927, he went as associate professor of medicine to the University of Rochester and joined the staff of the Strong Memorial Hospital as assistant visiting physician. From there, he went in 1928 to Rockefeller Hospital as associate, proceeding in 1930 as associate professor of medicine to Peking Union Medical College and as associate visiting physician, Peking Union Medical College Hospital, where he remained through 1934.

Returning to the United States, he became medical superintendent, New York Hospital, New York City, in 1936. In 1939 he filled the post of secretary, State Board of Medical Examiners, Department of Education, Albany, New York, during which time and until 1944 he was also assistant professor of medicine, Albany Medical College, Albany. He is a member of the Harvey Society of New York and of the Albany County Medical Society.

Dr. Hannon's medical background is such as to command the respect of all with whom he will come in contact, and he brings to the Executive Office of the Medical Society of the State of New York not only exceptionally varied medical training but also the dignity of a wide experience both in medicine and in the State Department of Education.

It is our considered opinion that American medicine, both to fulfill its wartime functions and to exercise its full scope and power in the postwar world, will need to develop further a quality to which it has not yet sufficiently directed its full attention; namely, the quality of medical statesmanship.

Medicine's relations with local, state, and national government and with the projected super-government of the future world will be vast, complicated, intricate, and can be properly and powerfully influential. It can aid, perhaps as no other agency yet created by mankind, in the cause of maintenance of the peace; it speaks all languages, crosses all borders,

flies to the stratosphere, goes under seas, enters all homes and hearts.

Yet medicine can be no better than the mind of man who has created it; no broader than his outlook on life; no deeper than the foundations he has put under it; no more forceful than the spiritual drive he puts behind it.

Our concept of the teaching of medicine has been somewhat limited by our closeness to it. Our concept of the practice of medicine has been too circumscribed in the past by what we thought were the limitations of the practitioners. Our relations with each other, with the public, with agencies of government have been erratically timid, sometimes querulous, often diffident, frequently formidable. There does not seem to have been developed as there could have been, a quality of leadership, either by our schools, our county societies, or our other representative bodies, which could be thought of and respected as consistent medical statesmanship.

The choice of Dr. Hannon to represent the Society at Albany seems a wise move in the direction of sound medical statesmanship. His personality, his background, his training, his wide and varied experience in many parts of the world, his acquaintance with legislators and legislative procedures should materially raise the already high public relations standards of the Medical Society of the State of New York.

Correspondence

To the Editor:

At a time when the Blue Cross, and many large hospitals, press for the inclusion of medical care with the benefits of group hospitalization contracts, the experience of the doctors of the city of Niagara Falls, New York, should be of interest to the physicians who are tempted to submit to professional exploitation as an inducement to Blue Cross subscribers.

In the October, 1943, issue of *Medical Economics*, Mr. Louis H. Pink stated that "Blue Cross had never attempted to control the relationship between the hospitals and the medical profession."

In the May, 1944, issue of *Medical Economics*, I pointed out that this statement was incorrect and that the Western New York Hospital Service Corporation had interfered vigorously in that relationship—that it had instigated a "putsch" in the Niagara Falls, New York, hospitals.

In the September, 1944, issue of *Medical Economics*, Mr. Carl H. Metzger, executive director of the Buffalo Hospital Service Corporation (Blue Cross), denied that it had instigated a "putsch" against the medical profession of Niagara Falls, New York. He admitted, however, that the Blue Cross Corporation put pressure on Niagara Falls Hospital trustees to achieve what he describes as "normal utilization" of group hospitalization coverage there. He stated further that at no time did the hospital service corporation attempt to influence appointments. When Mr. Metzger stated that the (Blue Cross) Corporation notified the (Niagara Falls) hospital trustees that it could not continue to operate the plan in Niagara Falls unless normal utilization were achieved, he did not state all that he did. He went further! How far he went the reader may now judge for himself. Here are Mr. Metzger's own words on the subject in a signed communication of April 27, 1944, attempting to explain the situation to a dissatisfied subscriber: "Second, we are not, we do not claim to be, and we recognize our inability to be an approval or rating body for member hospitals. It is true that the utilization of hospital service in Niagara Falls was away beyond normal. Investigation indicated that although these hospitals had been approved by the American College of Surgeons, the inspection for approval had evidently overlooked the fact that the requirement regarding medical staff organization was not being complied with. This we called to the attention of the hospitals."

Notice what they called attention to!—the hospitals' medical staff organization. They were not in a financial position at the time to ignore anything the Blue Cross called specific attention to. They needed money! The medical reader is left to conclude whether the Blue Cross' "calling attention," as he says, to medical staff organization, in such manner, under the circumstance did, or did not, constitute deliberate interference with medical practice. This interference started a "putsch."

It was proper for an executive director of a group hospitalization corporation to achieve what he thought was "normal utilization" of the coverage. But when he intruded on the domain of the inspectors for the American College of Surgeons, and "drew attention" specifically to medical staff organization and had it changed, he was decidedly "off the reservation!" He did exactly what the medical profession had been apprehensive of. He interfered with medical practice "in a big way" with a club over the heads of the hospital trustees.

The American College of Surgeons did not start the staff shake-up. The Blue Cross did. The hospitals of Niagara Falls, New York, had been inspected and approved by the American College of Surgeons for a number of years. But it remained for Mr. Metzger to decide "who was who" and "what was what"—and to coerce the hospitals.

Mr. Metzger also said "It is true that a reclassification of physicians and their appointments in various services was carried out by the medical staffs of the hospitals themselves." This statement

[Continued on page 82]

RENAL TUMORS SIMULATING GASTROINTESTINAL DISEASE

SAMUEL LUDASH, M.D., F.A.C.S., New York City

THE relative frequency with which renal tumors have been mistaken for gastrointestinal diseases, because of symptoms relegated only to the intestinal tract, has prompted this communication.

It is common knowledge that disease of one system can produce symptoms entirely in another. It has also been shown that pathology in one kidney might refer its symptoms to the opposite side of the body. Whether these phenomena are known as "reno-gastric reflex," "retroperitoneal syndrome," "renal-digestive reflex arc," or "reno-renal reflex," one thing they have in common—that is, all these terms have a neurogenic background or origin. It has been definitely shown by experimentation that the stomach, small intestine, cecum, transverse colon, kidney, and ureter have the same source of innervation. Such workers as Tixier (1897) and Tixier and Clavel (1929-1932), Head, Chauford, and Debray (1925), Papin (1925), and others have definitely proved this to be so.

Clinicians and research workers throughout the world attested to its occurrence by both clinical and experimental observations. It is only in the last twenty years that the literature has become voluminous with such reports. Cecil, in a study of 300 consecutive urological cases (1920), found that 28 per cent of urinary calculi and 30 per cent of hydronephrosis had only gastrointestinal symptoms. So misleading were these symptoms that 20 per cent of the former series and 30 per cent of the latter had exploratory operations because of inadequate diagnosis.

Similar experiences by other authors were encountered: Chauford and Debray (1925): "Reciprocal connection between renal and biliary lithiasis"; Smith (1933): "Gastrointestinal symptoms in hydronephrosis and renal calculi"; in later years, Abeshouse (1935), Grauss (1936), Beer (1936), Mertz and Hartsock (1936), Smith and Orkin (1939), and others.

It is only with the last-mentioned authors that there has been a study made of a series comparable to that of Cecil's. In Cecil's series four tumors of the kidney were mentioned. In the latter series Smith and Orkin (487 consecutive cases) showed that in 10.2 per cent, or 50 cases, a diagnosis of a digestive tract lesion had been made. One case of renal tumor was encountered. Chute and Kelly (8 cases), although reporting a much smaller series, also encountered one case of renal tumor. Beer, in his monograph, goes so far as to say that "reflex intestinal symptoms are rarely produced by tumor of the kidney."

A study, therefore, was made of all personal and service cases that had been seen at the Beth Israel Hospital for the past five years, either on the urological or other services. All cases were proved to be renal tumors of various kinds by pathologic study. In all, 33 cases were found. The oldest patient was 75; the youngest was 38; the average age was 54. There were 22 men and 11 women. Of the tumors, hypernephromas were the most common (22 cases, or about 65 per cent). Next in frequency were tumors of the renal pelvis (6 cases, or 17 per cent). Of these tumors 4 were malignant (carcinoma) and 2 nonmalignant (benign papilloma or fibrocpitheliomas). There were 3 cases of carcinomas of the kidney (or 8.5 per cent), one case of lipoma of the kidney, and one case of unknown pathology. Five cases (or about 15 per cent) were so masked by other than urologic symptoms and mimicked such diseases as carcinoma of the ovary, carcinoma of the transverse colon, possible gallbladder or liver malignancy, acute suppurative cholecystitis, that exploratory surgery was indicated. In none of these 5 patients was there at any time any indication of any urologic disease. Urines in all were practically negative; an occasional white blood cell was noted in 3. It is interesting to note that all 3 cases of carcinoma were included in this group. The other 2 were hypernephromas. Whether the type of tumor cell has any bearing on reflex activity is questionable.

Group I—Renal Carcinomas

In this group 3 cases were found. Peculiarly enough, none of these ever came to the urologic service. One was operated upon for a suspected ovarian cyst or pedunculated fibroid; the other two for suspected malignancy of the intestinal tract. At no time did any of these cases present a history relegated to the urologic tract. All symptoms pointed to the gastrointestinal system.

Case 1.—C. G., a 50-year-old female, had two admissions to the hospital over a period of a year and a half. Her chief complaint was pain in the epigastric region and about the abdomen for the past two years. This pain was increased with movements of any nature. Upon her first admission she was found to have an umbilical hernia, for which she was operated upon. Her symptoms still persisted. She returned to the hospital a second time, to the Gyne-

Associate Urologic Surgeon, Beth Israel Hospital, New York City.

cological service, one and a half years after her first operation, again complaining of pain in the abdomen. Her menstrual history was normal. This time a mass was found which almost filled the abdominal cavity. It felt movable, distinct from the liver, and extended toward the left, downward almost to the anterior superior spine. Its lowest border was not felt. Upon pelvic examination the mass did not move with the cervix. A preoperative diagnosis of either an ovarian cyst or a pedunculated fibroid was made. Operative findings were a carcinoma of the right kidney with metastases to the liver.

Case 2.—J. L., a 38-year-old white male, admitted to the surgical service, with complaint of loss of weight of 30 lbs. in the past 6 months, and pain in the abdomen, gaseous distention, and cramps. No urologic symptoms.

Physical examination revealed a chronically ill appearing white male. The blood pressure was 118/65, the pulse 90, respirations 22, temperature 100 F. Heart and lungs were negative except for slight dullness at lower left part of the chest posteriorly at the site of an old empyema incision. A firm, nodular mass could be palpated in the left hypochondrium, extending down to approximately the umbilicus on respiration. It was movable and could be ballotted anteriorly from behind.

Complete gastrointestinal series as well as a barium enema were done. All proved negative. The urine revealed a few white blood cells.

An exploratory abdominal operation was performed on July 30, 1936. Postoperative findings: A large carcinoma of the left kidney.

Case 3.—R. R. was a 49-year-old white female, complaining of pain in the epigastric region and nausea but no vomiting. The pain was aggravated by food. The pain sometimes radiated toward the right lumbar region. A mass could be felt upon physical examination in the right upper quadrant of the abdomen. Urine analysis was negative.

Preoperative diagnosis: Possible malignancy of transverse colon.

Operative findings: Carcinoma, right kidney.

Group II—Tumors of the Renal Pelvis

Another interesting feature but directly opposite in reflex activity is the group of tumors of the renal pelvis. Here no case ever presented anything but urologic symptoms—primarily hematuria, of one or more attacks, either scanty or profuse and usually painless, with no referred symptoms to the intestinal or any other tract.

Of the 6 cases found in this series 2 were benign (papillary fibroepitheliomas) and 4 carcinomas. Five came to surgery; one patient died before surgery, in uremic coma.

This type of renal tumor cannot be diagnosed early unless a given history of renal bleeding is encountered and thoroughly investigated. If there is a filling defect, no matter how small, in the renal pelvis, a second investigation during a nonbleeding period should be repeated, and if this condition is found again exploratory investigation of this organ is advisable. Only in this way must we assume our responsibility of detecting early renal tumors.

Case 4.—O. G. was a 65-year-old white man with a complaint of painless recurrent hematuria of one and a half years' duration. The patient had had a sudden episode of hematuria one and a half years before, accompanied by dysuria and occasional episodes of difficulty in starting stream. There was no pyuria. He never complained of any abdominal discomfort. The last attack of hematuria was twenty-four hours before admission. (See Fig. 1.)

Physical Examination: Heart and lungs were negative. There was no palpable mass in the abdomen. Liver, kidneys, and spleen could not be felt. There was tenderness over right kidney region.

Laboratory Data: Urine examination on admission was too bloody for accurate analysis. Nonprotein nitrogen was 50. Retrograde pyelograms revealed a filling defect of the right kidney pelvis. The left side was normal.

Preoperative diagnosis: Tumor of right kidney.

Nephrectomy was performed February 17, 1937.

Pathologic report: Carcinoma of kidney pelvis.

Case 5.—I. C., a 48-year-old white man, complained of bloody urination. For the past two months the patient had noted that his urine was rather dark. The evening before admission he noticed that his urine was frankly bloody. There was no dysuria, frequency, urgency, nocturia, or difficulty in voiding. There was no nausea, vomiting, fever or chills, and no loin or abdominal pain. (See Fig. 2.)

Physical Examination: Heart and lungs were negative. The right kidney was palpable. The left kidney was not felt. There were no masses.

Laboratory Data: Urine examination revealed numerous red blood cells and 8 to 10 white blood cells. Benzidine was 0. Nonprotein nitrogen was 37. Intravenous urography revealed a tumor formation involving the right kidney which dilated the pelvis and distorted its contour. This finding was verified by retrograde study. The opposite kidney pelvis was normal, with excellent function.

Nephrectomy was performed on March 3, 1939.

Pathologic report: Benign papillary fibroepithelioma of the kidney pelvis.

Case 6.—H. R. was a 60-year-old white man, complaining of intermittent pain in the back and hematuria for two years, attacks of severe pain in the right flank with gross hematuria, and passage of clots in the urine for three days. On admission the patient appeared undernourished and exhibited marked pallor and moderate cyanosis. There were dullness, diminished breath sounds, and crackling rales at the base of the right lung which x-ray later revealed to be due to thickened pleura with productive changes in the bronchial walls. The heart was moderately enlarged. Heart sounds were rapid, with a loud musical systolic murmur at the apex, transmitted to the axilla and the base. There was marked tenderness over the right kidney, which was not palpable. The urine was grossly bloody and

FIG. 1. Group II. Case 4 Large filling defect proved to be carcinoma of kidney pelvis

also contained numerous white blood cells The red blood cell count was 4,800,000; hemoglobin was 89; nonprotein nitrogen was 40.

On cystoscopy, blood could be seen pouring from the right ureteral orifice. A catheter could be introduced without obstruction. Neither retrograde pyelogram nor intravenous urography showed visualization of the right kidney. Intravenous indigo-carmine was returned in five minutes from the left side, but not on the right.

Operation: The right kidney was approached by the lumbar route. The kidney was found to be adherent, moderately enlarged, and engorged. The pelvis was incised but no tumor tissue could be curretted out. Nephrectomy was performed, and on sectioning the kidney a large adherent blood clot with tumor-like tissue was found.

Pathologic Report: Papillary fibro-epithelioma of kidney pelvis.

Case 7.—M. R., a 68-year-old white man who had been well until four weeks before admission, developed sharp, lancinating, colicky pain in the left lumbar region, radiating to the left hypochondrium and the angle of the left scapula. Hematuria developed simultaneously; frequency and nocturia (six to seven times) developed shortly afterward. He had lost 15 to 20 pounds in weight in the preceding four weeks. His previous history was completely negative.

Examination revealed a poorly nourished white adult, chronically ill male. Heart and lungs were completely negative. Blood pressure was 148/78.

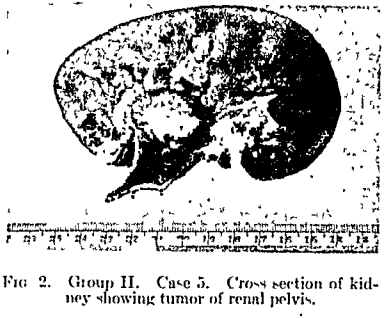

FIG 2. Group II. Case 5. Cross section of kidney showing tumor of renal pelvis.

Abdominal Examination: There was costovertebral tenderness on the left. The left kidney was enlarged and palpable but nontender. The abdomen was otherwise negative. The extremities were negative The prostate was small, smooth, and moderately enlarged.

Laboratory Data: Nonprotein nitrogen was 42 Glucose was 117. A Wassermann test was negative The urine was grossly bloody. There was a 3 plus reaction for albumin. The specific gravity was 1.026. On cystoscopy the appearance of the left ureteral orifice was normal in position. A catheter passed to 21 cm. with difficulty. Ten cc. of cloudy, bloody urine were retained on that side. No indigo-carmine came from the left side in thirty minutes.

Preoperative Diagnosis: Tumor of the left kidney.

Nephrectomy was performed.

Operative Findings: Squamous-cell carcinoma of the kidney pelvis.

Case 8.—M. K. was a 48-year-old man, with a history of having been kicked by a horse forty years before, following which a mass appeared in the left upper quadrant, associated with the occurrence of attacks of dull, gnawing pain in the left flank. He was admitted to the hospital thirty years before for similar complaints but refused operation and signed out after two days with the diagnosis of enlarged kidney. There had been no recent increase in the size of the mass. The pain had become more constant and severe in the previous month and he had become weaker and bedridden during this time. (See Fig. 3)

Physical examination revealed a cachectic-appearing male, with slight exophthalmos and an icteric tinge to the sclerae. The tongue was thick and ulcerated. The pharynx showed erythematous mottling. The teeth were poor. There were enlarged, hard lymph glands in the left supraclavicular fossa and enlarged lymph nodes in left axilla, which were not tender. A large mass was seen in the left upper quadrant, which did not move on respiration. It was hard and smooth and extended out from the costal margin to below the umbilicus, filling the entire left upper quadrant. It was only slightly

FIG. 3. Group II. Case 8. Flat plate shows large calcific shadow left kidney. Autopsy revealed carcinoma of kidney pelvis associated with calculus pyenephrosis.

tender and there was some left costovertebral tenderness, somewhat ballotable. A loop of gut could be felt running vertically across it. The liver could not be felt, and there was no ascites. Heart and lungs were negative. The rectal examination was negative.

Laboratory Data: The specific gravity of the urine varied from 1.006 to 1.020. It was alkaline, with 2–4 plus albumin, and was loaded with white blood cells and many red blood cells. The red blood cell count was 3.07 million. Hemoglobin was 69 per cent; the white blood cell count was 39,700, with 85 per cent polymorphonuclear leukocytes with 14 staffs, 13 lymphocytes, and 2 monocytes. The sedimentation rate was 100 mm. A Wassermann test was negative. The icteric index was 5.6. Glucose was 118. Nonprotein nitrogen was 150. Total protein was 7.5 Gm. The albumin-globulin ratio was normal. No tubercle bacilli appeared in catheterized urine specimen. A flat plate of the abdomen revealed a large mass occupying the entire left half of the abdomen, extending from the first lumbar vertebra to the level of the interspinous line. Within this mass are numerous calcific shadows varying from 0.4 cm. to $2^1/_2$ cm. Many of these stones have a laminated appearance. Above the shadow of this mass was the shadow of another mass. Intravenous urography showed very much diminished function, with no dye on the left side. X-ray of the chest revealed numerous calcific deposits at the roots of both lungs. The aorta appeared to be sclerotic. Blood pressure was 110/64.

Course: The patient came in to the hospital with a temperature of 102 F., which fell to normal on the third day. He was drowsy and slept a great deal. He was very uncooperative and refused everything that was attempted. His nonprotein nitrogen rose from 150 to 272 after two weeks, and his creatinin was 5.4. Despite the normal temperature, the white count remained elevated at 28,000, with 94 per cent polymorphonuclears. A biopsy was done on a supraclavicular node and the diagnosis was metastatic carcinoma of indeterminate origin. An attempt to do a barium enema was unsuccessful. Because of the lack of cooperation of the patient, intravenous therapy could not be continued and the patient was maintained on sedatives. He voided very little during the day, the amounts varying between 150 and 450 cc., despite a much larger intake of liquid. However, at no time was there any evidence of edema.

It was difficult to decide what the mass was. It was thought that because of the urinary changes and the high nonprotein nitrogen this mass might be kidney. In order for there to be a high nonprotein nitrogen, it was presupposed that there was involvement of the other kidney. Polycystic kidney with atrophy of the opposite kidney was suggested. Another suggestion was that this mass may have been spleen or perhaps a mass of retroperitoneal nodes. If so, then the possibility of a splenic vein thrombosis or retroperitoneal lymphosarcoma could account for the large mass.

The patient became drowsier and went rapidly downhill. He vomited on several occasions. There was a marked uremic odor to the breath. He developed ulcerations in his nose and on his tongue. He refused cystoscopy. His temperature became subnormal during the last week and he died of uremia two and a half weeks after admission. On the day before death he became dyspneic and many moist rales were heard throughout both lung fields. There were also twitchings. A congo-red test showed no evidence of amyloidosis.

Autopsy revealed that the mass was a very large kidney which contained many large stones and a large amount of pus. There was evidence of carcinoma within the pelvis of the kidney. There was no kidney on the right side. There were metastases to liver and lungs as well as to the mesenteric nodes. The spleen was slightly enlarged and posterior to the mass. The omentum and a loop of gut ran across the mass.

Case 9.—H. B., 63 years old, complained of hematuria of one year's duration. Three days before admission the patient felt pain in the right loin, followed by gross hematuria. Hematuria continued up to the time of admission. The past history was negative except for suprapubic prostatectomy in New York Medical Center two years before. He had been symptom-free since.

Physical Examination: The temperature was 99 F. The pulse was 116. Blood pressure was 205/130. The patient was a well-preserved white man, somewhat pale and anemic. The pupils re-

acted normally to light and accommodation The heart was enlarged to the left The aortic second sound was greater than the pulmonic second sound There was a systolic murmur at the apex The lungs were normal except for moderate emphysema There was mild clubbing of the fingers The abdomen revealed an operative scar and mild costovertebral tenderness on the right The kidneys were not palpable Rectal examination was negative Examination of the genitalia revealed a firm, irregular mass in the right testicle, with small hydrocele

Laboratory Data The urine was grossly bloody Hemoglobin was 64 per cent The red blood cell count was 3 05 million Nonprotein nitrogen was 60 Cystoscopy revealed grossly bloody urine coming from the right ureteral orifice Indigo carmine appeared in normal time, in concentration from the left side but not from the right Bloody urine came from the right side Kidney, ureter, and bladder examination and retrograde pyelography were done but were not satisfactory Intravenous pyelogram showed nonvisualization of the right side A retrograde pyelogram repeated showed marked deformity, with a filling defect of the right renal pelvis

On February 18, 1939, a right nephrectomy was done The pathologic report was carcinoma of the renal pelvis The patient made an uneventful recovery except for occasional elevation of the nonprotein nitrogen Before discharge, a right ureterogram was performed which showed no evidence of tumor

Group III—Lipomas

This type of tumor of the kidney really has no place in this discussion as it is not of a purely tumor nature It usually represents the replacement of destroyed renal tissue by fat and is most commonly found associated with chronic suppurative pyelonephritis or renal calculi It may sometimes be so marked that replacement may be complete, except for the renal pelvis surrounding a calculus It is for these reasons, I believe, that particularly all such tumors will give symptoms referable to the intestinal tract some time during their course

Case 10—M W was a 60-year old woman with history of pain in the epigastric region associated with nausea, which was aggravated by eating She had no urologic complaints She was sent to the hospital for observation

Physical examination A large mass was felt in the left flank, extending around anteriorly to the umbilicus The *urine was negative* but for a trace of benzidine and an occasional white blood cell Examination of the chest was negative A flat plate revealed a calculus in the region of the pelvis of the left kidney and also a small calculous fibroid in the pelvis Intravenous pyelogram was performed in order to determine whether the mass in the flank was kidney A pyelogram revealed that the left kidney was hydronephrotic, considerably enlarged, and that there was a large calculus near the ureteropelvic juncture At cystoscopy, no indigo-carmine could be obtained from the left kidney after eighteen minutes' observation However, from the right it appeared in four minutes in fair concentration

On July 7, 1938, on operation, the left kidney was found to contain no normal renal parenchyma and was surrounded by dense adhesions and a large perirenal lipoma

Postoperative Diagnosis Lipoma of the left kidney

Group IV—Tumor of Unknown Pathology

Case 11—A S, a 52-year-old white man, complained of attacks of vomiting of three months' duration The vomiting was associated with epigastric distress, which usually occurred in the morning and was not related to meals During the previous three months the patient had had moderate constipation, otherwise his past history was irrelevant

Physical examination revealed a well-developed male, not acutely ill The blood pressure was 140/70, pulse rate 96, respirations 26, temperature 98 8 F *Heart and lungs were negative, except for a* rough systolic murmur at the apex and over the aortic area In the left upper quadrant there was a large, firm, ballotable mass, filling the entire left side of the abdomen to the level of the iliac crest Rectal examination was negative

Laboratory Data The urine revealed 1 to 3 red blood cells per high-power field and was negative for benzidine The red blood cell count was 4,000,000, hemoglobin was 70 per cent The white blood cell count was 15,500, with a normal differential The sedimentation rate was 80 mm in forty five minutes Nonprotein nitrogen was 28

X-Ray Examination Intravenous urography showed nonfunction of the left kidney Retrograde pyelography revealed the calyces of the left pelvis to be dilated and elongated There was displacement of the upper third of the ureter toward the midline

On February 3, 1939, through a transperitoneal approach, an exploratory operation was attempted and an enormous retroperitoneal tumor was found to be occupying the left upper quadrant Tumor *tissue was taken for biopsy and the capsule of the* tumor sac was marsupialized so that the tumor was not located just below the anterior abdominal wall

Pathologic Report Malignant tumor of unknown nature

Eighteen deep x ray treatments were given and the tumor decreased markedly in size so that it was no longer palpable The patient made an uneventful convalescence and was discharged on March 29, 1939

Group V—Hypernephromas

This was the most common type of tumor found in our series (22 cases) Of this number 10 cases (45 per cent) presented themselves with only gastrointestinal symptoms and 12 (55 per cent) with hematuria as the first symptom Five

FIG. 4. Group IV. Case 15. Retrograde pyelogram of patient shown in Fig. 14—nephrectomy proved it to be hypernephroma.

of the 10 cases were first observed on the gastrointestinal service, where they had a complete series of gastrointestinal and gallbladder tests. Three others had an abdominal exploration on the surgical service, because of symptoms suggestive of an intra-abdominal tumor. Another died before any surgery could be done.

Only 4 case histories of this series will be illustrated, none of which came to the urologic service. Two had intravenous urograms done and were reported to have normal renal pelves. Another had a retrograde pyelograph taken only after an incision into the scalp for a sebaceous cyst had revealed a mass seemingly associated with the brain. The operation was immediately stopped. The fourth died in uremic coma before surgery could be instituted.

Case 12.—H. R., aged 58 years, entered the hospital complaining of pain in the left lumbar region for fifteen years, as well as abdominal distention and lower abdominal pain, and right upper quadrant pain for one day.

On examination the patient looked emaciated and the right upper abdomen was filled with a somewhat tender, firm, slightly nodular mass.

Intravenous urography showed no kidney pathology, but showed the right kidney to be markedly displaced by a mass in the right upper quadrant. All other x-ray examinations were negative except the gastrointestinal series, which revealed a distortion of the stomach and duodenum caused by external pressure.

A clinical diagnosis of metastatic carcinoma of the liver was made, but because of the duration of the mass an exploratory operation was advised by the medical consultant in the hope that the mass was not malignant.

The general condition of the patient before the operation was only fair. At operation a mass weighing 1,100 Gm. was removed from the region of the right adrenal, reported as hypernephroma. Following the operation the patient went into shock and in spite of immediate transfusion he died twelve hours after the operation.

Case 13.—L. P., a 60-year-old man, was admitted with complaints of pain in the right upper quadrant associated with constipation and vomiting on the first day. His temperature on admission was 103.6 F., pulse 108, respirations 28.

Examination revealed a generally soft, nontender abdomen, except for a very tender mass extending down from the right upper quadrant to the umbilicus. The blood count: 33,700 white cells, 85 per cent polymorphonuclears with 17 young staffs. Urine examination revealed many red blood cells. A Wassermann test was negative. The nonprotein nitrogen was 35. It was felt on admission that the patient had an acutely suppurative gallbladder.

Cholecystography was done one week after admission, the acute symptoms having subsided and the blood count having fallen to 8,000 white cells, with 74 per cent polymorphonuclears of which 4 were staffs. The plates showed normal gallbladder shadow, with a large oval mass beneath the gallbladder. Retrograde pyelography and intravenous urography were done, showing normal kidney pelves on both sides. The kidney on the right was displaced outward and to the left. There was no evidence of calculus. A mass was seen displacing the right kidney. In view of the persistence of the mass an exploratory laparotomy was done, at which time a huge hypernephroma of the right kidney was found. This was removed transperitoneally. The tumor was adherent to the peritoneal reflections on the outer aspect of the colon and also had to be dissected away from the gallbladder. There were also dense adhesions to the adrenal nerve. There was also a perirenal hematoma present which was removed en masse with the kidney tumor. A stab wound was made in the right loin in the retroperitoneal space, which was drained.

Postoperatively the patient made a good recovery on the first day, but voided only 3 ounces of urine in twenty-four hours. Nonprotein nitrogen was 69 on the second day. Despite all forms of stimulative treatment, the patient voided only 3 ounces of urine in three days and developed pulmonary edema and meningeal symptoms and died on the third postoperative day.

Case 14.—I. L., a 76-year-old man, first came to Beth Israel Hospital complaining of rectal pain, constipation, and abdominal cramps on June 28, 1939. Urine examination was entirely negative. A rectal polyp was found and removed. Complete physical

examination was otherwise negative He was readmitted on August 18, 1939, two months later, complaining of constipation and cramplike feeling in abdomen, but there were no urinary symptoms. At this time an abdominal mass was found and a tentative diagnosis of carcinoma of the intestinal tract was made Colon enema and gastrointestinal work-up was negative. A few red blood cells were found in the urine A genitourinary consultation revealed a possible tumor of the left kidney X-ray of the chest showed metastases to the lung The patient was not operated upon because of rapid debility and uremia, from which he expired

Case 15.—S. L., a 55-year-old man, although complaining of and treated for gastrointestinal symptoms for five years prior to his present complaint without any relief, now sought advice because of a small mass on the top of his head, which was thought to be a sebaceous cyst. He was referred to a very competent surgeon, who attempted to remove this under local anesthesia, but immediately realized after his initial incision that he was dealing with a tumor mass. X-ray of the skull and a biopsy specimen showed involvement of the brain due to hypernephroma. He was then advised to have a urologic investigation. He never complained of any urologic symptoms but with cystoscopic and pyelographic studies a diagnosis of tumor of the left kidney was made This was removed and found to be a hypernephroma. (See Fig 4.)

Comment

It is quite apparent from this survey that one should not be satisfied with a routine study of one system where intermittent symptoms persist in the presence of negative roentgenographic and laboratory findings. The disease must be looked for in other systems. Only through a study of "system pathology" or "system diagnosis," as suggested by Von Lichtenberg and Winsbury-White, can one readily appreciate the fact that a disease process may involve more than one organ or one system With the advent of intravenous urography, all previous objections to cystoscopic inspection are now overcome. Yet too much reliance cannot be given this method. Retrograde pyelograms should always follow the use of intravenous urography where there is any doubt as to the exact interpretation. One method should be an adjuvant to the other. Never should it be taken for granted that either one replaced the other.

We feel relatively certain from this study of renal tumors that any case presenting disturbing abdominal symptoms with negative findings should have a complete urologic investigation. In some cases, as illustrated above, even if this is done it is impossible to make a definite diagnosis. Exploratory operations were necessary to arrive at a conclusion.

Summary

1 A survey of 33 cases of renal tumor are reported

2 Of this number, hypernephroma (65 per cent) is the most common.

3 Those cases in our series of tumor involving the renal pelvis (17 per cent) failed to cause any gastrointestinal reflex symptoms. Whether this is coincidental or not is uncertain, but it is mentioned for what it may be worth

4. The reflex activity was directly opposite in the cases of carcinoma of the kidney. Here all simulated gastrointestinal or other intra-abdominal diseases for which laparotomies were performed.

5 Twenty-three cases (or 69 per cent) of the entire series had gastrointestinal symptoms. This also includes symptoms referable to the gallbladder.

6 A fair number of these showed no urologic findings

SOCIAL HYGIENE DAY TO BE FEBRUARY 7, 1945

The American Social Hygiene Association has announced that the annual observance of National Social Hygiene Day is scheduled for Wednesday, February 7, 1945

As in previous years, educational efforts will be concentrated during the entire week in an endeavor to promote a [illegible] of the need for combat-

[illegible] ygiene Association will send to any group which is planning a meeting their new kit of "Social Hygiene Day Program and Publicity Aids."

The kit includes press releases, platform talks, radio scripts, drafts of proclamations for use by mayors or governors, new educational leaflets, a poster for advertising meetings, news about motion

MENTAL HYGIENE COMMITTEE HONORS GENERAL KIRK

The National Committee for Mental Hygiene has elected Maj. Gen Norman T Kirk, Surgeon General of the Army, as one of its six new members, in recognition of his "unusual awareness of the importance of skilled psychiatric treatment in the Army."—*J.A.M.A., Nov. 25, 1944*

BRONCHIAL ASTHMA

A Report of 141 Cases

EMANUEL SCHWARTZ M.D., F.A.C.P., Brooklyn

THERE were 141 cases of asthma admitted to the medical service of Long Island Hospital as service and private cases over a five-year period from 1937 to 1941, inclusive. There were 18 cases in 1937, 18 cases in 1938, 30 cases in 1939, 24 cases in 1940, and 51 cases in 1941. In this group the preliminary causative factors were specific antigens, such as inhalants, foods, and bacteria, or a combination of all three. The infections were characterized by purulent sputum or evidence of chronic sinusitis, and were secondary and superimposed on primary allergic bronchial asthma.

There were 78 women and 63 men.

The tabulation of the ages of the patients at the time of admission, according to decades, was as follows:

14–20	21–30	31–40	41–50	51–60	Over 60
11	19	30	34	36	11

Twelve patients dated the beginning of their symptoms to the first decade of life, and in 65 patients, or 46 per cent of the group, the symptoms began between the ages of 10 and 40. They started between the ages 41 and 50 in 31. Onset in 26 occurred in the years between 51 and 60; 7 were over 60 at the onset. The duration of symptoms ranged from two and a half months to fifty-two years. Seven patients had their initial attack following pneumonia, 26 following an acute upper respiratory infection, and 23 stated that a "cold" usually ushered in an attack.

Family History

There was some evidence to indicate that there was a tendency to inherit susceptibility to asthma rather than any other allergic condition. Thirty-seven of the 141 patients gave a family history of asthma.

Associated Allergic Manifestation

The associated manifestations of allergy in these cases were as follows:

Perennial allergic rhinitis	24
Seasonal hay fever	20
Urticaria	13
Allergic eczema	5
Gastrointestinal allergy	6

Sixty-eight patients, or 41 per cent of the group, gave a past personal history of an associated allergy.

From the Department of Medicine, Long Island Hospital.

Symptomatology

The outstanding symptoms, irrespective of the type of asthma, were dyspnea, wheezing respirations, and cough. All 141 patients gave a history of paroxysmal attacks of cough, wheezing respirations, and dyspnea; 11 patients had hemoptysis; 9 patients were markedly cyanotic; 6 patients complained of vomiting and epigastric distress. The outstanding symptom was dyspnea, accompanied by a wheezing type of respiration. Cough was the next in importance, and was not absent in any of the cases. It usually preceded the attack of dyspnea or wheezing. It was noted that as the attacks proceeded the cough in these cases increased in severity, and the patients found it difficult to bring up any expectoration. Toward the end of each attack the cough became looser, and the expectoration less difficult. With the disappearance of the wheezing and dyspnea the cough, in most cases, lasted several days. All patients complained of expectoration during an attack. The expectorated matter was usually thick and gelatinous in character. It usually was colorless, unless there was an associated bronchial infection, in which case it was yellowish or greenish. The hemoptysis occurring in 11 patients was due to violent coughing efforts; 6 of these patients had bronchiectasis. One patient whose x-ray examination showed active pulmonary tuberculosis did not have hemoptysis even during a severe attack. Coryza either preceded or accompanied the onset of the paroxysm in 24 cases. It consisted chiefly of sneezing and a profuse watery nasal discharge. These cases were diagnosed as allergic rhinitis. Pain in the chest occurred in 5 patients; in 2 patients it was caused by a thickened pleura, and in the other 3 it was muscular in origin, because of prolonged and repeated attacks of cough and dyspnea. Of the 13 patients with associated urticaria, 4 complained of it during an asthmatic attack. In 3 it was caused by aspirin sensitivity, and in the others the causes were unknown. The duration of the attacks varied from one half hour to three weeks, and the duration of the intervals was between twenty-four hours and ten months.

Physical Signs

Physical signs found on examination of these patients with asthma depended largely upon the time at which the examination was made, and

upon the duration and character of the asthmatic state All 141 patients exhibited on first examination physical signs characteristic of an asthmatic attack The typical wheeze in most of the patients was audible, even without a stethoscope The prolongation of both phases of the respiratory cycle, particularly of the expiratory phase, was noted Sibilant and sonorous rales were heard, usually over the entire chest Seventeen patients showed evidence of emphysema on examination One patient had clubbed fingers and toes

Nose and Throat Examination—The nasal septum was noted to be deviated in 17 cases engorgement or enlargement of the turbinates was present in 29 cases, with polyp formation in 16, 22 had swollen and pale mucous membrane and toxic mucosa was present in 3, 22 patients had had successful tonsillectomies performed previous to admission, 22 had diseased tonsils and on 8 of these tonsillectomies were performed without any effect on the severity or number of asthmatic attacks

Examination of Sinuses—An existing sinus infection was determined by clinical and roentgenologic means, by the nose and throat and x-ray departments, in 32 out of 60 cases so examined The final end results of rhinologic treatment in our series were difficult to estimate Although beneficial results were obtained in occasional cases, there were comparatively few patients in whom relief from asthma was complete or lasting Closer cooperation between the internist and the rhinologist in the thorough study and treatment of these patients is still essential if the best results are to be obtained

Chest Examination—The pulmonary findings were summarized as follows 96 chest x ray plates were taken, 14 were negative, 38 showed chronic bronchitis, 6 showed bronchiectasis, 28 showed emphysema, 2 showed fibrotic thickening, one showed congestion, one showed active tuberculosis, one showed an old tuberculous lesion, 2 showed pleuritis, 2 showed thickened pleura one showed eventration of the diaphragm, one showed cervical rib, and there was one case of pneumoconiosis and one of bronchopneumonia

Other Diagnoses

Other diagnoses noted by physical examination in this series were one case of bronchopneumonia, 10 cases of hypertension, one case of pneumoconiosis, 3 cases of diabetes, one case of cor pulmonale, 9 cases of arteriosclerosis with myocardial damage, one case of right bundle-branch block, one case of rheumatoid arthritis, 2 cases of syphilis, one case of active tuberculosis, one case of mitral regurgitation and stenosis, 3 cases of inguinal hernia These conditions had no relationship to the severity, duration, or number of asthmatic attacks It is of interest to note that there was only one case of active tuberculosis in this series

Laboratory Findings

Urine—Examination of the urine showed nothing characteristic Three cases showed positive reactions to sugar

Blood Pressure—The blood pressure in 10 cases was high, normal in 123 cases, low in 8 cases

Blood Count—In all cases differential blood counts were performed Values ranging from 0 to 16 per cent eosinophils were encountered, although neither of these figures was common, 86 of the patients had a count of 5 per cent or under, 28 patients had an eosinophilia of 10 per cent or over, 27 had an eosinophilia of 5 to 10 per cent The average count was 6 8 per cent It was impossible to differentiate on the basis of the eosinophil count between infective and noninfective asthma

Blood Chemistry—The blood chemistry in 70 patients showed normal values for urea, uric acid, and creatinine The blood sugar ranged from 60 mg to 122 mg in 62 cases, and in the 3 diabetic patients readings were recorded as follows 250 mg , 280 mg , and 320 mg Only 5 patients had a blood sugar below 80 mg one was 60 mg , one 72 mg , one 78 mg , one 75 mg , and one 79 mg

Analysis of Gastric Contents—Examination of the gastric contents was done in 18 patients The values for free HCl ranged from 25–80 degrees, and for total acidity from 40–100 degrees

Basal Metabolic Rate—The basal metabolic rate was determined in 15 patients, and ranged from −12 to +19, one case was +19, one case was +17, and one case −12, the remainder being within the −10 to +10 limits

The blood Wassermann, Kahn, or Hinton tests were done in 141 cases One patient had a positive Hinton, another patient who had tertiary syphilis gave a history of a 4-plus spinal Wassermann previous to entering the hospital 140 patients had negative serology, including the patient with tertiary syphilis

Summary

1 One hundred and forty-one cases of bronchial asthma admitted to the medical service at Long Island College Hospital from 1937 to 1941 are studied statistically from the standpoint of sex, age, family history of allergy, associated allergic manifestations, symptomatology, physical findings, nose and throat examination, x ray of chest, eosinophilic counts, blood chemistry,

gastric analysis, basal metabolism, and serologic examinations.

2. There were 78 women and 63 men.

3. Sixty-five patients dated the beginning of their symptoms between the ages of 10 and 40; 12 during the first decade of life; 31 between 41 and 50; 26 between 51 and 60; and 7 after 60 years of age.

4. Thirty-seven of the 141 patients gave a family history of asthma.

5. Sixty-eight patients, or 41 per cent of the group, gave a past personal history of an associated allergy.

6. One hundred and forty-one patients complained of repeated paroxysmal attacks of difficult breathing, cough, and wheezing of the chest; hemoptysis occurred in 11; pain in the chest in 5; and symptoms of sneezing or a profuse watery nasal discharge, or both, either preceded or accompanied the onset of an attack in 24 cases.

7. The entire group of 141 patients was examined during an attack and showed the typical physical findings of bronchial asthma.

8. An existing sinus infection was present in 32 out of 60 patients so examined.

9. Of 96 chest x-ray plates taken, 14 were negative; 38 showed chronic bronchitis; 6 bronchiectasis; 28 emphysema; 2 fibrotic thickening; one congestion; one active tuberculosis; 2 pleuritis; 2 thickened pleura; one eventration of the diaphragm; one cervical rib; one pneumoconiosis; and one bronchopneumonia.

10. Three patients in this group had diabetes mellitus.

11. The eosinophil counts were summarized as follows: 86 patients had counts of 5 per cent or under; 27 had an eosinophilia between 5 and 10 per cent; and 28 had an eosinophilia of 10 per cent or over. The average count was 6.8 per cent.

12. The blood pressure was normal in 123 cases, high in 10, and low in 8.

13. The blood sugar in 70 cases so examined ranged from 80 mg. to 122 mg. in 62 cases, and in the 3 diabetic cases 250 mg., 280 mg., and 320 mg. Five cases showed a blood sugar value below 80.

14. The values for free hydrochloric acid and total acidity in the gastric contents were within normal range in 18 patients so examined.

15. The basal metabolic rate, determined in 15 patients, ranged from −12 to +19.

16. All 141 patients had negative serology for syphilis.

Brooklyn, New York

"ADVANCES IN MEDICINE" SERIES AT MT. SINAI HOSPITAL

A second series of lectures on "Advances in Medicine" is being given in Blumenthal Auditorium, 1 East 99th Street, New York 29, New York, by the medical staff of Mt. Sinai Hospital on Wednesday evenings at 8:30 P.M.

On January 10, Dr. Joseph H. Globus, associate neurologist, will speak on "Recent Advances in Our Knowledge of Cerebral Vascular Accidents." On January 24 Dr. Richard Lewisohn, consulting surgeon, will discuss "Recent Advances in Cancer Research." The lecture on February 7 will be "Recent Advances in the Treatment of Glaucoma" by Dr. Robert K. Lambert, attending ophthalmologist. On February 21 Dr. Murray H. Bass, attending pediatrician, will give a lecture entitled "Recent Advances in Pediatrics." Dr. Isidor C. Rubin, attending gynecologist, will speak on "Recent Advances in the Study of Sterility" on March 7. On March 21 Dr. Richard M. Brickner, associate neurologist, will discuss "Recent Advances in Cerebrospinal Scleroses." On April 4, Dr. Abraham Hyman, attending surgeon, will speak on "Recent Advances in Diseases of the Urinary Tract." The lecture on April 18 will be "Recent Advances in Experimental Hypertension and Therapy" by Dr. Bernard S. Oppenheimer, consulting physician. Dr. Harry Sobotka will close the series on May 2 with a lecture entitled "Recent Advances in the Physiology of Vitamin A."

PUBLIC HEALTH CANCER ASSOCIATION FORMED

The Public Health Cancer Association was recently organized to meet the particular need of persons engaged in cancer control activities in federal, state, city, and other official agencies. Active membership is limited to professional workers in such official cancer programs, and officers include Drs. Herbert L. Lombard, Boston, president; Raymond V. Brokaw, Champaign, Illinois, vice-president, and Morton L. Levin, Albany, New York, secretary-treasurer. Included in the membership of the executive committee are Drs. Frank L. Rector, Lansing, Michigan, Louis C. Kress, Albany, New York, and Edmund G. Zimmerer, Des Moines, Iowa.

Representatives attending the organization meeting felt that the American Association for Cancer Research adequately covered that field, that the American Cancer Society is chiefly engaged in lay educational work, and that the new organization would meet the particular needs of full-time employees engaged in cancer work in the official agencies. It was also felt that such an association would be of value in furthering cancer control by conducting an annual meeting and a cancer symposium in connection with the annual session of the American Public Health Association. While representatives from about eleven states attended the organization meeting, the membership will not be limited solely to this group.—*J.A.M.A., Nov. 25, 1944*

SCOPE OF AN INDUSTRIAL MEDICAL SERVICE

HAYNES HAROLD FLLLOWS, M D , New York City

EMERGENCY medical care for workers is increasing on such a scale that today it is commonplace and expected In scope it may be as simple as a first aid kit available to all and sundry who self treat, using a little first aid knowledge, or it may be so extensive as to supply complete medical, surgical and hospital care for employees and their families And while the art of medicine is as old as civilization, industrial medicine, so-called, is a relatively recent development and its rapid expansion a current situation

Probably our experience at the home office of the Metropolitan Life Insurance Company in New York City is a typical example of how an industrial medical service comes into being Prior to 1911 we had no real medical service for our employees, although advice and emergency treatment were available through doctors who were doing regular life insurance work and who carried on the service to employees as a sideline In the spring of 1911 we had at the home office a trained nurse who was assisting in the formulation of plans for building and equipping what was to be our sanatorium at Mount McGregor, New York As soon as it became known among the employees that there was a nurse in the Medical Division, they began to come to her for advice about their personal problems and for first aid care It became apparent quickly that a doctor would be of great help because so many of the questions and conditions were beyond the capacity of a nurse Consequently, after some discussion and planning a small room was fitted up and equipped and a full-time nurse and part-time physician were on duty each day Even this was soon inadequate and a well equipped and amply large dispensary was the next step forward, all of this taking place within a year In 1914 the pre-employment physical examination of applicants for employment and an annual physical examination for all Company employees were decided upon, and increased space equipment, and personnel were necessary The chief purpose of both of these activities was to detect unrecognized abnormalities among average healthy persons at a time when correction might logically be expected to be easiest and most beneficial This was the beginning of the present health and medical welfare program for employees which has gradually increased to our present service

Today the health program for home office employees is administered by a section of the medical division known as the Medical Rest Rooms There is a medical and surgical dispensary, separate quiet rooms for ill male and female employees temporarily indisposed or waiting to be sent home or to a hospital, rooms equipped for eye testing, and physiotherapy rooms for the administration of infrared and ultraviolet light treatment and diathermy, and for teaching exercises for the correction of postural defects when requested by a physician

The laboratory facilities available include those for urinalysis, basal metabolism tests, blood counts typing and serologic examinations, electrocardiography, and x-ray examination Fluoroscopes are available in rooms adjacent to the examining rooms, and these are used routinely by all physicians when examining ill employees or when making physical examinations

The medical rest rooms are under the supervision of a full time physician The medical staff is composed of men and women selected for their general medical qualifications and specialized training who are on duty part-time, some in the morning and some in the afternoon In addition there are two full-time specialists, one in psychiatry and one in tuberculosis While much of our work is of a minor or routine character, yet it is a great advantage to have practically all of the recognized specialties represented in our "group"

The service available to employees consists of medical advice, first aid or emergency treatment, diagnosis, and the completion of special laboratory examinations, particularly in cooperation with, or at the request of the family doctor There is no attempt or intent to act in the capacity of the private or family physician

A nursing staff is an integral part of the organization and in addition to the nurses on duty in the rest rooms at the home office, there are nurses who visit home office employees during absences from work because of illness

A record room is maintained, where the complete medical history of each home office employee is kept on file For each individual there is a folder containing the pre-employment examination, each annual examination, notes made at each dispensary visit, reports of all laboratory, electrocardiographic, and x-ray examinations, and a record of all absences due to illness with the reports of the visiting nurse The record room is in charge of a trained statis

Read at the Annual Meeting of the Medical Society of the State of New York New York City May 10 1944

Assistant Medical Director Metropolitan Life Insurance Company

tician who makes monthly and yearly reports, and also reports of special studies.

When an employee reports for duty after an illness, he goes first to the medical rest rooms, where he must receive medical approval before returning to work.

Employees may come to the rest rooms at any time during the day if they feel ill or wish advice upon a personal health problem. They first report to the record room and then proceed to the dispensary. The medical record of each employe is taken from the file and is sent to the doctor whom the employee consults. Most cases are of a trivial character and after some simple treatment or medication the patient is able to return directly to work. Others, however, are too ill to continue at the office and are advised to go home and consult the family physician if necessary. As one would expect in a group of this size, we frequently see seriously ill persons who need immediate hospitalization, which we arrange for, taking the wishes of the clerk, his family, or family doctor into consideration.

It is scarcely possible to have a fully equipped medical division without taking advantage of the unique opportunity to make practical observations of various kinds. The reports of the study of some of our problems have been made available from time to time to industry and the medical profession, and three will be summarized here.

In keeping with our interest in the search for unrecognized disease, we were trying to find a simple and satisfactory method to carry out the routine serologic testing for syphilis as early as 1930. To examine a cooperative patient in private practice and to carry out a case-finding study on thousands of working persons of average health are two different problems. The requirements for such a program are maximum accuracy, reliability, lack of uncomfortable or disabling wound, ease of collection and use of a small amount of blood, a simple technic, low cost, and, most important, a method of taking care of the positive reactors. After considerable discussion we decided upon a microprecipitation test of a specimen of blood collected from a finger puncture and have used, singly or in combination, the Kahn, Kline, and Mazzini tests.

Anticipating the possibility of embarrassing moments in the disposition of persons with tests found positive in a routine examination, we devised a procedure which we thought would bring no objections. A doubtful or positive test was checked in two weeks and if it remained doubtful or positive the person was asked to come to the office, where it was explained that the recent blood test gave an unsatisfactory result; why, we did not know, inasmuch as there are many reasons for such a result, some of no importance and some of real significance. In order to answer satisfactorily all the questions involved, an appointment was always made for the employee to see a syphilologist who had the facilities and the experience to arrive at a diagnosis and, it was also explained, this would be without expense to the employee. Following this careful and consistent diagnostic workup, the cases were classified as specific, doubtful, or nonspecific, and a report was sent to the family doctor whenever requested. Those few in need of treatment were advised as to the length of treatment and the approximate cost, and selected the method which he could best afford—private physician or clinic. Of all those examined only about $^1/_2$ of 1 per cent were diagnosed as specific and in need of treatment.

All patients with positive or doubtful serology are tested annually and from this follow-up study a good deal of information regarding "false positives" has been gained. It is of more than passing interest that the consultant who so generously worked out a solution to this problem with us was selected as Chief of the Division of Serology at the Army Medical School and has supervision of the same problem for the Army.

During the past decade increasing attention has been paid to the degenerative changes of middle and later life, with particular emphasis on arteriosclerotic heart disease and hypertension. The reasons for this are the apparent or real increase in the prevalence of these conditions and the fact that little is known of their cause, therapy, or prevention. Knowledge of this kind can be gained best through a continuous systematic observation of a group of average normal adults who, as they grow older, develop changes inherent in the process of aging. Such a study must, of necessity, cover a period of many years.

Since nearly all home office employees who have reached the age of 40 remain until retirement age (age 60 for women; age 65 for men), a group of about 3,000 average adults in middle and later life is available for such a long-term study. In 1929, plans were made to begin a series of annual observations on this group, to be carried on for an indefinite number of years. Accordingly, in 1930 a routine electrocardiogram was included in the annual examination of clerical employees 40 years of age and older. And on reaching the age of 40 all other employees are examined in the same way. In 1937 and 1938 routine roentgenograms of the heart were taken to obtain additional information regarding heart size, and these examinations are repeated at suitable intervals.

Through the use of these objective methods,

supplementing the physical examination, it is believed that progress has been made in establishing an early diagnosis We have seen some conditions which have a small beginning, scarcely deviating from normal unless viewed serially, and over the years show steady though slow progress Other changes fluctuate for a variable length of time before becoming established and another group shows massive changes as the first variation from normal frequently accompanied by slight or vague symptoms or none at all This is certainly not true in all cases but it is surprising to see how often it is true Having found such a case what is to be done about it? Certain practices have been adopted as an approach and others are planned Fourteen years of work have resulted in increased knowledge but large gains lie in the future

Statistical studies correlating the electrocardiographic physical and roentgenographic data have been and are being made The technic of carrying out a study of this character presents quite a puzzle Among other things it must be feasible and simple enough to warrant inclusion in a busy routine schedule Also it must be comprehensive without including unessential details We know that progress has been made but suggestions and opportunities to discuss these studies with other interested persons are welcomed It seems logical to expect that similar studies carried on in other places with different groups will lead to more rapid progress if the results are pooled

Undoubtedly the most profitable and gratifying results so far have come from our tuberculosis control program Prior to 1927 the detection and subsequent care of cases of pulmonary tuberculosis among home office employees represented a real problem At that time a rather high incidence of active disease about four cases per thousand, chiefly in the advanced stage was found among home office personnel each year After the installation of roentgenographic apparatus in 1926 and the more frequent use of this type of examination, the discovery of an occasional case of active tuberculosis soon after the usual pre-employment or annual physical examination made it obvious that it was not possible to depend upon even the most careful physical examination to detect early cases The use of x ray examination in chest diagnosis was not so common as it is today—as a matter of fact unless the clinical symptoms and physical findings agreed with the x ray the latter was apt to be discounted or ignored Since we knew what had to be done, we planned a method for routine case finding and hoped it would work We installed fluoroscopes in 1928 to supplement all physical examinations and used them routinely as a method of determining which patients should be x-rayed This greatly reduced the expense and increased the efficiency of handling the tuberculosis problem among home office employees The results have been striking, conclusive and continued—the incidence of new cases needing treatment has decreased by more than three quarters and for years the large majority of the cases has been discovered in the minimal stage Inasmuch as the incidence of tuberculosis among applicants for employment has shown no real or continued decrease since 1928 we feel that our present favorable position is a reflection of our program which is to make sure that no definite lesion is present at the time of employment and to take stock of the situation by an annual routine fluoroscopic examination of all employees We believe we were the first organization of any sort to adopt such a procedure and over the years it has paid large dividends both tangible and in satisfaction

The report of these three typical studies shows the opportunities open to industrial medicine and usually not found in the clinic hospital, or private practice of medicine which deal almost exclusively with 'sick people The chief value of carefully planned systematic observations carried out upon a group of working people of average health is in the early detection of unrecognized disease and also in the determination of criteria to define "average health' Certainly the results of the examinations of draftees, with the large rejection rate would indicate the necessity for a nationwide program to raise our present average well above its unsatisfactory level It is in the field of such activity that industrial medicine has its true scope and opportunity

Discussion

Dr L Holland Whitney*, *Nassau New York*—Dr Fellows has covered the activities and objectives of a well rounded medical program

It is interesting to note that the trend of medical activities is toward prevention and this is of course commendable I am particularly impressed by the very complete cardiac survey which has been in effect for some time It is quite apparent that Dr Fellows has been aware of the fact that here was an unusual opportunity to accumulate a vast store of information, which is unique Hardly any of the cases have cardiac complaints Broken down by age groups this will make interesting and valuable data

Venereal disease control and recognition is another important contribution I hope many other industrial groups will be able to take advantage of a similar opportunity Case finding and therapeutic

industrial vision studies. Our preliminary studies point up several things. First, that the expense of an industrial vision program can be met by the resultant decrease in the number of eye accidents. Second, we can improve placement technic and reduce cost by placing the worker in the job for which he is visually qualified, as well as physically qualified. Third, that an eye protection program, to be successful, cannot be divorced from an eye correction program. We are enthusiastic about the chances of making a real contribution to a subject about which little is known.

Dr. Fellows is to be congratulated on the excellent medical program which he has outlined. This comprehensive approach to the field of industrial medicine should serve as a stimulus to those of us who have been so fortunate as to be here.

PRESIDENT AGAIN DEDICATES BIRTHDAY TO FIGHT AGAINST PARALYSIS

Dedicating his birthday for the twelfth consecutive year to the fight against infantile paralysis, President Roosevelt, in a letter released on December 8, declared that the fight against this vicious disease enemy "is a fight to the finish and the terms are unconditional surrender."

His letter, written to Basil O'Connor, president of The National Foundation for Infantile Paralysis, approved the latter's request for centering the 1945 Fund-Raising Appeal of the National Foundation around the celebration of Mr. Roosevelt's next birthday, January 30, 1945. The period for the Fund-Raising Appeal and the March of Dimes to the White House will be January 14-31, Mr. O'Connor announced.

Pointing out that the 1944 epidemic was the second largest in the history of the disease in the United States, Mr. O'Connor wrote the President that the voluntary contributions of the American people had made it possible for the National Foundation to put the largest polio-fighting army in history into the field to battle it.

"Due in large part to this fact, far more than half of those whom infantile paralysis struck down this year will again be going about their tasks with faith and hope and confidence, because their fellow Americans have made it possible," wrote Mr. O'Connor. "Further, while everyone afflicted by infantile paralysis is assured the best of medical care and treatment, at the same time there is going on a vast program of research to find a preventive and cure of this disease.

"Unremitting research will provide the key which will unlock the door to victory over infantile paralysis. The fashioning of this key takes time and money and the talents of a host of eminent scientists. That work is going on constantly—supported by National Foundation grants operative in more than fifty institutions throughout the country; that work is going on by virtue of the mandate of the American people who, aware of the threat of recurrent epidemics, are resolved that this disease must be conquered."

In reply, President Roosevelt wrote, "The work of The National Foundation for Infantile Paralysis and its chapters glows as one of the brightest pages in the history of how a nation of free people, working together, seeks to assure for its children the priceless gift of health.

"It is good to know that while the infantile paralysis casualties of 1944 and former years are receiving the aid they need, there is going on apace an ever-expanding program of research seeking the prevention and cure of the disease. I feel as you do that the value of this research cannot be overemphasized. Treatment, no matter how adequate, cannot win this war against a disease aggressor; but scientific research put in motion by the American people through their support of the National Foundation will unquestionably conquer this disease.

"We face formidable enemies at home and abroad," wrote the President. "Victory is achieved only at great cost—but victory is imperative on all fronts. Not until we have removed the shadow of the Crippler from the future of every child can we furl the flags of battle and still the trumpets of attack. The fight against infantile paralysis is a fight to the finish, and the terms are unconditional surrender."

AWARD OFFERED FOR PAPER ON GLAUCOMA

A prize of $500 for the most valuable original paper adding to existing knowledge about the diagnosis of early glaucoma or the medical treatment of noncongestive glaucoma is being offered by the National Society for the Prevention of Blindness, 1790 Broadway, New York 19, New York.

This award will take the place of two separate prizes of $250 each which were announced some time ago.

Papers may be presented by any practicing ophthalmologist of the Western Hemisphere and may be written in English, French, German, Italian, Spanish, or Portuguese. Those written in any of the last four languages should be accompanied by a summary in English.

The award will be made by the Society with the guidance of an ophthalmologic committee composed of Drs. John N. Evans, Frank C. Keil, Daniel B. Kirby, Arnold Knapp, John M. McLean, R. Townley Paton, Algernon B. Reese, Bernard Samuels, Kaufman Schlivek, Mark J. Schoenberg, Manuel Uribe Troncoso, and David H. Webster.

CHEMOTHERAPY, MICROBIOTIC SUBSTANCES, AND RADON—THEIR LOCAL USE AS THERAPEUTIC AGENTS IN OTOLARYNGOLOGY

S J Crowe, M D , and Arthur T Ward, Jr , M D , Baltimore, Maryland

THIS report is intended as a brief summary of studies of four local therapeutic agents which have proved themselves to be of great value in otolaryngology, they are the chemotherapeutic agent sulfadiazine, the bactericidal and bacteriostatic agents tyrothricin and penicillin, and the radioactive gas radon

Sulfadiazine solution[1] is 2 5 per cent sulfadiazine in ethanolamine The solution has a pH of 8 7, is nontoxic, and is readily absorbed by tissues Local use makes unnecessary the saturation of the entire body and thus prevents various toxic reactions associated with sulfonamides

This nonirritating solution is invaluable in treating infections of the pharynx, nasopharynx, and the ear, particularly when they are due to beta hemolytic streptococci In treating the common cold this solution has no effect on the virus but inhibits or kills the secondary bacterial invaders of the mucous membranes By frequent use of this local treatment one reduces the duration of coryza, lessens the disagreeable symptoms, and prevents complications such as otitis and sinusitis This is accomplished by *building* up a high local mucous membrane sulfadiazine level

Bactericidal agents derived from micro-organisms open up a new and important field of therapy for the otolaryngologist In 1939 René Dubos[2] found that a specific bactericidal agent could be obtained from the aerobic sporulating soil bacterium, Bacillus brevis From peptone cultures of this organism, a water-soluble and a water-insoluble fraction have been obtained The water-soluble fraction is not bactericidal, whereas the water-insoluble fraction is highly bactericidal This bactericidal crystalline material is called tyrothricin It has been further fractionated into gramicidin and tyrocidine, both of which appear to be polypeptides Gramicidin is bactericidal in general for gram-positive organisms, while tyrocidine is bactericidal for both gram-positive and gram-negative organisms The action of gramicidin is believed to be due to interference with one or more metabolic systems of the individual bacterium

Tyrothricin is extremely stable either as the crystalline powder or in alcoholic solution Clinically it is usually used as a 1 1,000 to 1 10,000 solution made from 2 per cent alcoholic solution, diluted with sterile distilled water This mixture is a suspension which in vitro studies show may kill all gram-positive organisms, but pneumococci and streptococci are more susceptible than staphylococci in dilutions of 1 1,000,000 It must be stressed that tyrothricin is very toxic intravenously and subcutaneously, but harmless when used locally as a contact agent, since it is not soluble in water and is not absorbed

The third bactericidal agent is penicillin Of the great varieties of this mold, Fleming's[3] strain most closely resembles Penicillium notatum It is from this strain that the crude penicillin used in our work was made Penicillium may be grown in rectangular flat-bottomed bottles on a liquid amino acid medium, at room temperatures In seven to twelve days it entirely covers the surface of the medium with a thick, wrinkled, gray-green growth The so-called harvesting of the material must be done at the proper pH moment, as its greatest activity is lost unless it is stopped at about pH 7 to 7 5 The underlying liquid is then passed through a Seitz filter The clear, amber-colored *filtrate contains* the crude bactericidal agent, penicillin Its strength is determined by titration against standard bacterial cultures This crude penicillin will only retain its potency if kept frozen Under these conditions potency will be maintained for about two months

Unlike tyrothricin, purified penicillin, which is water-soluble, may be given intramuscularly or intravenously as well as used locally Excretion is by way of the kidneys Penicillin is bactericidal, but mostly it acts as a bacteriostatic agent, its effectiveness being due to interference with multiplication of bacteria Penicillin differs from the sulfonamides in that its action is not nullified by pus, peptones, or para-aminobenzoic acid It is nontoxic

In general, like tyrothricin, penicillin is bacteriostatic for gram-
anaerobic streptococ

For over two years we have tested clinically tyrothricin and crude penicillin as local agents[4,5] in a large number of cases covering every phase of otolaryngology For a comprehensive and true estimation of values it was found necessary to make a thorough bacteriologic study of each individual case In each case complete studies of each organism and its reaction to tyrothricin and penicillin in various dilutions were ob-

From Johns Hopkins Hospital Baltimore Maryland

served. A method of bacterial titration was used.

A summary of findings shows that these agents either inhibit or kill most strains of staphylococci, streptococci, and pneumococci. It must be stressed that there is not only bacterial group sensitivity, but also a bacterial strain sensitivity. In a group of 59 patients with hemolytic Staphylococcus aureus infections, titration showed that 9 were insensitive to tyrothricin and 12 to crude penicillin. Irrigation of the sinuses with the therapeutic agent which most effectively inhibits or kills the infecting bacteria will give better results in acute maxillary sinusitis than in chronic maxillary sinusitis due to the same organism. The explanation for this is that the bacteria in the acute phase are on the surface of the mucous membrane, and in the chronic stage they are deep within the glands and submucosal tissue. Therefore in chronic infections it is necessary to use these microbiotic agents along with the usual surgical procedures.

By irrigating an antrum, for example, during the operation, and soaking the packing with the bactericidal agent of choice, the postoperative result is a sterile or bacteria-inhibited field.

Tyrothricin is not absorbed and is effective only when it comes in direct contact with bacteria. Penicillin is absorbed to a greater extent, but to be most effective should be in direct contact with the infecting bacteria for several hours.

Bacterial growth curves, using various concentrations of the bactericidal agents, when plotted against time, show that tyrothricin acts almost immediately, whereas crude penicillin reacts after an interval of several hours.

By knowing what organisms one is dealing with, by knowledge of these new therapeutic agents, by titration tests to determine the agent of choice, we believe one can more intelligently evaluate results and effectively treat otolaryngologic infections. Through the proper use of these local agents along with operative procedure, it is believed that the postoperative edema, pain, purulent discharge, and consequent formation of infected granulation tissue are greatly reduced or completely abolished. Likewise, postoperative care and hospitalization time are reduced.

The fourth therapeutic agent, radon, has been used in the Johns Hopkins Hospital for sixteen years in the treatment of certain conditions that cause deafness. The technic and specifications of the radon nasopharyngeal applicator are as follows: The radioactive element is a glass capillary tube $1^1/_2$ cm. long which fits into a brass screw tube 2 cm. long and with a lumen of 1.5 mm. The thickness of the tube wall is 1 mm. of brass. This unit screws into the handle, which is 13 cm. long. The glass capillary contains sufficient radon gas to produce about 1,000 millecuries. Four grams of radium in solution produces about one liter of nitrogen, helium, hydrogen, oxygen, and radon daily. By sparking off the hydrogen and oxygen and by freezing the remaining gas with liquid air and through a complicated process utilizing differences in melting point, pure radon is obtained. By use of the gold leaf electroscope and comparison of the radon capillary to a standard of 50 mg. of radium whose strength is known, one can obtain from calculated tables the millecuries produced at any hour of any day. Multiplication of this number by a factor which gives 2.0 Gm. minutes gives one the standard dose and time, which sixteen years of work has proved to be safe and effective. Radon applications are given once monthly up to four doses. However, before each treatment the nasopharynx is carefully examined with the nasopharyngoscope to determine whether treatment is necessary. Since brass filters out most of the Beta rays, this applicator allows irradiation mainly with the mild Gamma rays.

Since radon is not available everywhere, experiments are at present under way in which applicators containing 50 mg. of radium sulfate are used. Since the millecurie output of this amount of radium, using a 1 mm. brass filter, would require a long time for each application, a different filter must be used. The filter of choice would be Monel metal 0.3 mm. in thickness. This applicator would require one month after the radium has been placed in it to reach equilibrium. Before use its output should be calculated at the Bureau of Standards. A dosage equivalent to that obtained by the radon applicator described above would be the same for each application—about $6^1/_4$ minutes; Beta ray output would be higher in this applicator than in the brass radon applicator first described.

The principles of the recognition, treatment, and prevention of hearing impairment center about the following concepts:

1. Impaired hearing for high tones, with good hearing for low tones, is the earliest symtom of middle-ear as well as of inner-ear deafness.

2. Recurrence of adenoids after operation on children is so common that it must be regarded as normal. This recurrent lymphoid tissue may impair the function of the eustachian tubes and cause a low grade chronic tubotympanic catarrh which may lead to progressive deafness.

3. Recurrent or hyperplastic nodules of adenoid tissues in and around the pharyngeal orifice of the eustachian tubes are so located that they cannot be removed surgically.

4. Every type of deafness seen in adults is also found in children. In most types the earliest symptom is a loss of hearing for high tones, and for their recognition the tones above 8,000 *double vibrations must be tested.*

5. In order to have good hearing the eustachian tubes must function normally. Impaired function of the eustachian tubes in children is caused by regrowth of the lymphoid tissue in the nasopharynx. In order to discover this condition the nasopharynx must be examined with the nasopharyngoscope.

6. Early recognition of impaired hearing for high tones, long before the hearing of speech is affected, and irradiation of the nasopharynx to restore the patency of the eustachian tubes, is the only method for prevention of progressive deafness of this type. The only hope is early recognition and treatment, before irreparable damage to the mucous membrane of the middle ear and ossicular chain has occured.

7. Lymphoid tissue is so sensitive to radiation that the dose employed in the treatment of the nasopharynx is far below the amount that could cause any irritation or injury to the mucous membranes or surrounding structures.

Aside from the preventive treatment of deafness, the applications of radon therapy have been so broadened and extended that today it is one of the most useful therapeutic agents in the field of otolaryngology.

Radon is applicable to patients of all ages. Especially in infants and young children, recurrent otitis media, caused by chronic infection of the nasopharynx associated with lymphoid hyperplasia, usually can be cured promptly if radon is applied to the nasopharynx and sulfathiazole powder is insufflated locally into the canal, after carefully removing all discharge. Nasopharyngitis and the associated chronic cough are also benefited by this procedure. Radon is a most useful agent in cases of nasal obstruction due to hypertrophied adenoids in infants. The frequency and severity of acute coryza are reduced when lymphoid tissue has been thoroughly removed, by either surgical operation or irradiation.

Radon is also of value to patients who are either too ill or too poor a surgical risk for operative procedure, and for those in whom the adenoids have recurred following surgical removal. This is common in children. Radon used for patients in the outpatient department and in private offices often make hospitalization, anesthesia, and surgical operations unnecessary. This is particularly valuable in this period when almost all hospitals are overcrowded.

With a word of caution, we offer an observation as yet unproved. About nine months ago it was observed that among the hundreds of children being treated for the prevention of deafness there were a number with asthma. Many were allergic to the usual inhalants, but had failed to respond to desensitization, removal of the allergic agent, or change in diet. These patients had hypertrophied adenoids, and a history of frequent colds associated with asthmatic attacks. Many required adrenalin injections to relieve the acute attacks. Typical asthmatic attacks occurred at intervals, varying from two or three days to a month. Some had a seasonal relationship. Following radon treatments the severity and frequency of the attacks became less and in some patients the asthma disappeared altogether. One patient with a history of weekly attacks has had no asthma during six months of observation.

We have under way a research program for adult and child asthmatics, in which each case is carefully studied from the pediatric, the otolaryngologic, and the allergic medical standpoint. Only a long-range program will determine the validity of the above observations. Even if only certain types of asthmatic patients are benefited, the radon treatment will be worthwhile.

Theoretically, the effect of radon applied to the nasopharynx in these cases might be caused by reduction of secretions, changes in the absorption of allergic substances by nasal and nasopharyngeal tissue, or removal of the nasopharyngeal "culture tube" where sensitizing bacteria may thrive.

Summary

A 2.5 per cent sulfadiazine solution spray is nontoxic, is rapidly absorbed by mucous membranes, and when used frequently and in sufficient amounts will inhibit the growth of pyogenic organisms, particularly of beta hemolytic streptococcus, in the upper air passages. It is valuable in the treatment of infections of the pharynx and nasopharynx and for the control of the associated cough. If treatment of acute coryza is started early there is a reduction in the duration of the disagreeable symptoms and an almost complete absence of complications.

Tyrothricin, water-insoluble, is isolated from cultures of the aerobic sporulating B. brevis and has been further fractionated into gramicidin and tyrocidine. When used locally in suspension it inhibits the growth of certain organisms, in general the gram-positive group. It is extremely toxic intravenously. It is most valuable in the treatment of acute infections, and as a supplement to surgery in the treatment of chronic infections.

Penicillin is not toxic, either locally, intravenously, or orally. It is water soluble and is

isolated from the mold P. notatum. It interferes with multiplication of bacteria, and is slower acting than tyrothricin. In general it inhibits the gram-positive group of bacteria, but as isolation of the active principle continues, there are indications that it may be effective against a much broader group of bacteria.

Organisms may become resistant or fast to both penicillin and tyrothricin. Some strains of a bacterial group (especially of staphylococci) may be entirely unaffected by either agent, or may vary enormously in their sensitivity. Anaerobic streptococci, and the Lancefield B group, so often found in otolaryngologic conditions, are not affected by sulfonamides, but are sensitive to both tyrothricin and penicillin. For a better evaluation and interpretation of clinical results we must make bacteriologic studies on each patient.

Radon or radium salts, applied through a small applicator to the nasopharynx, have proved themselves invaluable in the prevention and treatment of certain forms of deafness associated with obstruction of the eustachian orifices. If they are carefully used there are no burns, crust formations, or disagreeable symptoms following treatment. This is based on observations at the Johns Hopkins Hospital on their use in children and other patients for the past sixteen years. In many cases, end results are more satisfactory than those following surgical removal of the adenoids, since lymphoid tissue is an integral part of the mucous membranes of the nasopharynx and is so diffuse that it cannot all be removed at operation. Recurrence after operative removal is so commonly found that it must be regarded as normal.

Aside from its use in the treatment or prevention of deafness, irradiation has wide uses in many other conditions of the nasopharynx. Observations on its use in patients with asthmatic bronchitis are mentioned.

In conclusion, the object of this report is to arouse interest in these four local therapeutic agents, so that their larger use may prove and extend their true values.

CLINICAL DEMONSTRATION IN VENEREAL DISEASE

Opportunities to observe demonstrations of venereal disease patients and to participate in discussions of diagnosis and treatment will be afforded New York City physicians at the Rapid Treatment Center at Bellevue Hospital. Starting Saturday, January 6, at 10:00 A.M., and on the succeeding three Saturday mornings, practicing physicians will be shown how the Center treats its cases of venereal disease by the latest methods.

The demonstrations will be under the direction of Dr. Evan Thomas, Dr. Ruth Thomas, Dr. Gertrude Wexler, and other staff members. Interested physicians should report to the office of Dr. Ruth Thomas at the opening of each session. Her office is in the Rapid Treatment Center in the R & S Building of Bellevue Hospital at First Avenue and 28th Street. Entrance is through the main gate between East 27th and East 28th Streets and then to the left.

SCIENTIFIC EXHIBITS

1945

ANNUAL MEETING

Applications for space for the scientific exhibits should be made directly to

Dr. J. G. Fred Hiss,
505 State Tower Building,
Syracuse 2, New York,

Chairman of Subcommittee on Scientific Exhibits of the Convention Committee.

Exhibits dealing with Industrial Health are especially desired.
The Annual Meeting will be held April 30–May 3, 1945, Hotel Statler, Buffalo.
The list will be closed on January 20, 1945.

PETER IRVING, M.D., *Secretary*

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the February 1 issue and will concern "The Rh Factor in Therapy."

Uses and Abuses of Quinidine

DR. CARY EGGLESTON: This is a series of exercises you are all familiar with, but it always reminds me to a certain extent of "Information, Please" in that recently it has become utterly unrehearsed and all you have is an interlocutor and several victims who have been more or less preselected so that we would be sure they would be here.

Today we are going to talk about a drug which, unfortunately, is rapidly disappearing from our armamentarium, largely on account of the war—namely, quinidine. Like quinine, it is becoming more and more difficult to obtain; that is, in any adequate supply. I have just today had a conference with a pharmacist who is appealing to the O.P.A. for the release to him of an additional supply of quinidine for his clients. It is true that a good many patients who require quinidine can get along, perhaps, without it without too great suffering, but many patients who really require quinidine find it extremely difficult to get along without it. So far as I am aware we have no satisfactory substitute for quinidine, so today we are going to discuss quinidine with the full recognition that it is difficult to come by. We hope that that situation will be corrected.

Quinidine was introduced in about 1914 as a result of observations made by the late Dr. Wenckebach on a patient of his who traveled a great deal to Java. This patient had auricular fibrillation and he turned to Dr. Wenckebach one day and said, "Doctor, I know how to stop this." Dr. Wenckebach was taken aback, and said, "Tell me how? I have never known of it." The patient said: "I noticed that when I go to Java and take my regular daily dose of quinine to protect me against malaria I am always free from these attacks of fibrillation." Shortly thereafter Dr. Wenckebach was transferrred from his professorship in Leyden, Holland, to Vienna, and there he invoked the assistance and aroused the interest of a young man named Frey, who undertook to study, at Dr. Wenckebach's suggestion, the various cinchona alkaloids to determine which of those, if there were any difference between them, was the more effective, and it was Frey who first drew attention to the fact that quinidine is more effective than any of the other cinchona alkaloids.

Dr. Gold, I would like to ask you very briefly to review the essential pharmacologic actions of quinidine upon the heart and its mechanism.

DR. HARRY GOLD: Quinidine has several actions upon the heart. The most important one from the standpoint of its therapeutic use is the depression of the rhythmicity of the heart muscle. It prolongs auricular, ventricular, and auriculoventricular conduction. Its further action in raising the refractory time of auricular muscle appears to be responsible for bringing a circus movement to an end.

There are, in addition, central actions of quinidine which are important in connection with its toxic effects (cinchonism).

DR. EGGLESTON: Dr. Deitrick, what do you consider to be the clinical indications for the use of quinidine?

DR. JOHN B. DEITRICK: Of foremost importance is its use in ventricular tachycardia which sometimes arises in the course of coronary occlusion; but it is useful for ventricular tachycardia from any cause. It has value in auricular fibrillation due to Graves' disease, in patients in whom normal rhythm was not established by thyroidectomy and/or adequate quantities of iodine.

It should be used to establish normal rhythm in paroxysmal tachycardia and fibrillation from whatever cause. I believe that would about cover it.

DR. EGGLESTON: Would you use it for the control of multiple premature beats?

DR. DEITRICK: In my experience it usually takes so much quinidine to eliminate premature beats—say, 0.2 Gm. three times a day—that most patients find it more troublesome to take the drug than to get used to the premature contractions.

DR. EGGLESTON: That is to say, you think the premature beats are of less importance to them than the maintenance of a regimen?

DR. DEITRICK: That is right.

DR. GOLD: Did Dr. Deitrick mean to omit auricular flutter?

DR. DEITRICK: I did not mention it because I personally would not prefer to use quinidine for auricular flutter.

DR. EGGLESTON: Dr. Gold, do you agree or disagree with Dr. Deitrick's answer or any part of it?

DR. GOLD: I think on the whole I would agree. I think quinidine has value in auricular flutter also. Perhaps one might add that quinidine is applicable only to certain disorders of heart rhythm and is of no value except occasionally in an indirect way, in relation to the problems of failure.

DR. EGGLESTON: There is one problem which has frequently been brought to the fore in the use of quinidine—namely, its use along with digitalis in the patient who has a disorder of cardiac rhythm and who has had congestive failure, and has been receiving digitalis for the latter. There are those who believe that the combination is contraindicated or at least hazardous. Others use the combination quite freely and without alarm. What is your feeling, Dr. Gold?

DR. GOLD: I think it is a good plan to avoid the use of quinidine in the patient who has had large doses of digitalis. Experimental evidence obtained in our laboratory shows that the heart under the influence of a great deal of digitalis becomes especially susceptible to certain toxic actions of quinidine. In the dog, after toxic doses of digitalis, a relatively small dose of quinidine sometimes produced complete cardiac standstill or ventricular tachycardia. The dose was sometimes surprisingly small, equal to about 3 grains of quinidine intravenously for a man in the case of auricular arrest. The cases of poisoning by quinidine reported in the literature are for the most part found in patients who have been under the influence of digitalis, and the question that has always been in our minds is whether the digitalis did not in many of those contribute to the toxic effects which had been attributed to quinidine alone.

DR. EGGLESTON: Dr. Pardee, you undoubtedly have had a good deal of experience on this point with your patients. What is your reaction?

DR. PARDEE: My reaction to the giving of digitalis and quinidine together is that I see no pharmacologic reason for it, and no therapeutic benefit to be obtained. I should think that the patient either needs to have the abnormal rhythm interrupted by quinidine or to have the heart failure treated by digitalis. The first thing to treat is the failure. When the failure has subsided and the patient is in good enough condition so that you don't fear there might be thrombi in the auricles, you might attempt to restore normal rhythm. Then you would use quinidine. To use the two together for any length of time makes no sense to me.

DR. EGGLESTON: Theoretically, of course, there is objection to their use simultaneously in that the actions of digitalis, in so far as they influence auricular fibrillation, should theoretically tend to perpetuate fibrillation, while the actions of quinidine are in the direction of terminating fibrillation.

DR. DEITRICK: It has been our custom here, as I recall it, when we wished to abolish auricular fibrillation, to digitalize the patients first and then give them quinidine.

DR. EGGLESTON: Did you stop the digitalis before you gave the quinidine?

DR. DEITRICK: Yes. First we gave digitalis. We then stopped it for not more than twenty-four hours, and then gave quinidine. The theory was that the digitalis might prevent the increase in ventricular rate which sometimes occurs in the course of the use of quinidine. Is that correct, Dr. Stewart?

DR. HAROLD STEWART: We usually do not give the two drugs at the same time. We stop the digitalis and start the quinidine the next day.

DR. EGGLESTON: Of course, that is tantamount to giving the two at the same time, because the digitalis action is so prolonged.

DR. STEWART: In actual experience we had no difficulty with that.

The idea that digitalis fixes auricular fibrillation seems to be fiction. We see patients with auricular fibrillation revert to normal rhythm while taking the digitalis. Patients with hyperthyroidism after operation revert to normal rhythm even though they may be taking digitalis. I think that on occasions digitalis prevents recurrent transient auricular fibrillation.

DR. EGGLESTON: I did not mean to imply that digitalis actually promoted or tended to fix fibrillation, but, based upon demonstrable actions, the effect should be in that direction. Clinically, in actual usage, I would quite agree with you that digitalis has no influence which we can detect upon the prolongation of paroxysmal fibrillation and often prevents its occurrence, and, moreover, frequently patients will revert spontaneously to a sinus rhythm from auricular fibrillation, although they may at that time be well under the effects of digitalis.

DR. STEWART: I might ask Dr. Gold about the dosage. He spoke of small amounts of quinidine in the animal experiments, but of large amounts of digitalis. Were those toxic amounts

of digitalis, or would they correspond to clinical doses?

DR GOLD The doses of digitalis were very large—about 50 per cent of a fatal dose for a dog Under these conditions a dose of quinidine which in the normal dog exerts no striking effect sometimes precipitates ventricular tachycardia, or auricular or ventricular standstill One can't assume that such a combined action will occur in humans in the range of usual therapeutic doses, but the possibility isn't to be ignored There are cases in which quinidine precipitated a ventricular standstill in humans, also ventricular tachycardia Those were often in digitalized patients They resembled very closely the effects observed on dogs

DR PARDEE Dr Gold, isn't it true, or hasn't it been observed, that the doses of quinidine which are likely to produce ventricular standstill or ventricular fibrillation are the smaller doses, and that larger doses do not tend to do that so much?

DR GOLD I don't know Here is one type of experience A man, 54 years old, developed coronary thrombosis Signs of congestive heart failure followed in a few days He was therefore digitalized After a maintenance dose for several days, an electrocardiogram showed a long P-R interval which was interpreted as a digitalis effect

From the very beginning, before digitalis was started, there were ventricular premature beats of multiple foci, sometimes two or three in a row They didn't seem to be influenced by digitalis and there were no gastrointestinal symptoms of digitalis toxicity While the digitalis was continued, the patient was given 5 grains of quinidine sulfate three times a day I would not know whether you consider that a large or a small dose, but it was continued for three days and on the third day the patient developed an attack of syncope, with cold clammy sweat The nurse thought he was dying, but he came out of that attack spontaneously No one knew just what had happened The two drugs were continued and two days later there occurred a similar attack This time the house officer happened to be there There was no heartbeat during the onset of syncope This was followed by tachycardia, during which the syncope began to disappear The patient could recall no details of the event The quinidine was discontinued and during the next four weeks of observation with digitalis alone there were no further attacks

Analogous experiences have been recorded in the literature

DR EGGLESTON Dr Gold isn't it true that it is a bit difficult to interpret the causes under circumstances such as those? I take it this was an acute infarction?

DR GOLD About a week after the onset

DR EGGLESTON We know that unexpected and unpredictable disturbances in cardiac mechanism may occur at any time within the first two or three weeks following acute infarction There are instances, however, of sudden death following the use of quinidine which are very well authenticated and for which no cause has been found postmortem I recall very dramatically one of the earliest experiences we had with quinidine at Bellevue Hospital It was not on my service, but Dr. John Wyckoff selected from the Outpatient Department a young man, seemingly entirely healthy——

DR GOLD I remember him

DR EGGLESTON He seemed entirely healthy except that he did show auricular fibrillation Dr Wyckoff took the boy into the hospital and studied him in all ways, prior to administering quinidine He gave him quinidine and the boy ceased to breathe, his heart having stopped very promptly after either the first or the second dose of quinidine At that time the doses were not in excess of 0 3 Gm , or 5 grains An autopsy showed no cause for the boy's death There are other similar authenticated cases I don't recall whether in that patient digitalis had been administered before My assumption is that it had not been, since the boy showed no signs of congestive heart failure

DR GOLD I'm certain that the proper combination for the synergistic toxicity of digitalis and quinidine is not frequently encountered, but since animal experiments show the possibility, and human cases sometimes reproduce the design, measures should be taken to guard against it

DR EGGLESTON We ought not to harp too much upon the dangers of quinidine, because quinidine has a definite place in the therapeutic armamentarium of the modern physician It is a drug that is used widely and with a great deal of safety, and, if intelligently used, with a good deal of success

DR PARDEE I should like to ask one more question before we leave this matter Do you think, Dr Gold, in view of the danger of the combination of these two drugs, which we all admit, that it would be advisable to leave the patient off of digitalis long enough to have the digitalis almost entirely eliminated from his system before giving the quinidine to restore normal rhythm in the presence of auricular fibrillation?

DR GOLD The major part of the digitalis should be eliminated before the quinidine is started

DR PARDEE Is that your practice?

DR. GOLD: It is when there isn't an urgent situation of greater hazard, making it unwise to wait. A good example is a patient with coronary thrombosis who on the third day suddenly develops a rapid heart action of 220 a minute and the doctor gives him digitalis before he finds out it is ventricular tachycardia. The patient is in shock. Quinidine is the only drug which will slow this rhythm. There is no choice but to give it at once even though he has had a great deal of digitalis. One shouldn't try to abolish the ventricular tachycardia in these cases, but only to slow it markedly. If you try to abolish the ventricular tachycardia, you may cause cardiac standstill in such cases because, owing to auriculoventricular block, their ventricle cannot respond to the auricular impulse.

DR. EGGLESTON: There are a number of practicing cardiologists and research cardiologists right here in the room. We have heard from Dr. Pardee and Dr. Gold.

Dr. Werner, what has been your experience, and what is your practice with reference to the use of quinidine?

DR. E. A. WERNER: I had worked at the clinic of Wenckebach. Several fatalities from the intravenous injection of quinidine occurred there. The autopsy reports did not reveal very much. As to my practice, I am very cautious in using quinidine, particularly in patients who come to the clinic and who are not subject to control. In the material we have here, which is quite extensive, there are comparatively few indications for the giving of quinidine.

DR. EGGLESTON: I should take up the indications more specifically in a few minutes. Have you ever seen a fatality which you could attribute to quinidine?

DR. STEWART: No.

DR. PARDEE: I have seen only one and that was in the first private patient I ever gave it to. She was a young girl who had, I believe now as I did at the time, an active endocarditis as well as a certain amount of heart failure. I now would never give it to such a patient. She had an embolus shortly after she resumed normal rhythm.

DR. JOHN B. DEITRICK: Has anybody ever seen acceleration of the ventricular rate in patients with auricular fibrillation as the result of quinidine, in consequence of which they develop failure?

DR. EGGLESTON: That was pointed out by Sir Thomas Lewis in his early study on quinidine.

DR. PARDEE: I have seen patients forced into failure by the continued administration of quinidine. They were given it for a number of days—ten days, perhaps two weeks—much longer than it should have been given.

DR. GOLD: If one gives the average patient with auricular fibrillation a dose of quinidine intravenously, the first thing that may happen may be that the ventricular rate will go up considerably. That is because of the fact that quinidine blocks the vagus and accelerates the rate in much the same way that atropine does. That isn't often seen after oral administration.

In the treatment of a patient with auricular flutter, the auricles often beat at about 350 and the ventricle at 175, there being a 2:1 auriculoventricular block. Sometimes, as the auricles are slowed down by quinidine, let us say to about 250 a minute, auriculoventricular conduction improves and 1:1 rhythm develops. In consequence of this the ventricular rate, which was about 175, rises to 250 a minute. This sometimes produces symptoms.

STUDENT: What nervous mechanism is released to make the rate go up?

DR. GOLD: It isn't the release of a nervous mechanism. It is merely a matter of the capacity of the auriculoventricular node to conduct at different rates of excitation. At a rate of 350 it is refractory and conducts only half of the impulses; at a rate of 250 it may not be refractory and may conduct them all. If the beats are too close together every other beat falls in the refractory period and only half of them get through.

DR. EGGLESTON: These same points were brought out in some of the earlier studies on quinidine. I remember very distinctly that in the publications of Sir Thomas Lewis which appeared in the *Lancet* he emphasized particularly the need for following the apex rate of the heart during the administration of quinidine and for avoiding the continued administration of quinidine if the apex rate rose above 200, if I recall the figures correctly.

Dr. Deitrick, do you use quinidine in fixed fibrillation?

DR. DEITRICK: No, I would not give it at all.

DR. EGGLESTON: Why not?

DR. DEITRICK: Because the return of the normal rhythm is only transient. It seems to me wiser to allow the body to make adjustments to one or the other, rather than to shift from fibrillation to normal rhythm and back again.

DR. EGGLESTON: At the time quinidine was introduced in medicine, Dr. Stewart was on the staff of our sister institution, and Dr. Alfred Cohn was much interested in quinidine. They gave it to a good many patients with auricular fibrillation. Dr. Stewart, did you use it in the patients with fixed fibrillation in contradistinction to the paroxysmal or transient type of fibrillation?

DR. STEWART: Not very often. We take

several factors into consideration (1) whether the patient is disturbed by the irregularity, (2) the size of the heart In those with a very large heart, one is more likely to encounter thrombi and accidents with the return of the normal rhythm and the regular forceful contraction of the auricles There is also the matter of failure If the patient had heart failure in the past or has prolonged heart failure I would think twice not to use it The decision to use it is based chiefly on these facts there never has been any heart failure, the heart is not unduly large, the patient is greatly disturbed by the irregularity In most patients, you can control the rate so much better when they have auricular fibrillation than when they have normal rhythm, particularly those with heart failure

Dr Eggleston Dr Pardee, you spoke in passing about a patient of yours who died, the first patient upon whom you tried quinidine I gathered from what you said that that patient died as a result of embolus

Dr Pardee Yes

Dr Eggleston A good deal has been written in the literature about the dangers of embolism when the auricular fibrillation is checked and synchronous contractions of the auricles take place What has been your experience about this and what is your feeling?

Dr Pardee I think it is a very real danger I have seen the same thing happen when auricular fibrillation spontaneously reverted to normal without the use of quinidine, and also when it reverted during the course of digitalis I think it is very important to attempt to decide whether or not there might be such auricular thrombi before you give quinidine to a patient You do it somewhat along the lines that Dr Stewart had suggested The size of the heart is important, particularly the size of the auricles, also the degree of cardiac insufficiency If failure is marked you would expect to have thrombi, particularly if it has recently been severe

Dr Eggleston You wouldn't use it in congestive heart failure?

Dr Pardee No If a patient with fibrillation has congestive failure I would not consider using quinidine to secure a normal rhythm I think it should only be done in a patient whose failure has cleared up, and whose functional capacity has reached a high rating

Dr Eggleston It would seem, then, that the consensus here with reference to the use of quinidine in the patients with the so-called fixed type of fibrillation is that for the most part quinidine is unnecessary, that there are certain very real hazards connected with its use, particularly the hazard of dislodging the embolus from the intra-auricular thrombi, and that there is likelihood of only temporary benefit

Dr Pardee But I think it would be a shame to leave the impression that it is not a very useful procedure in many patients with fibrillation to cause reversion to normal rhythm

Dr Eggleston Are you speaking of the fixed fibrillator?

Dr Pardee I am speaking of the fixed fibrillator who does not have severe heart failure even though he may have had auricular fibrillation for a long period of time I have seen a number of these patients who persisted with normal rhythm long enough before they again reverted to make it well worth while—that is, a year, two years, or more

So I feel somewhat more optimistic than your summarizing statements indicated

Dr Eggleston I am very glad you spoke up Maybe I had better appeal to Dr Stewart for his opinion

Dr Stewart I agree with Dr Pardee's statement

Dr Eggleston Dr Gold, I think you ought to come into this discussion

Dr Gold Do I understand that in a patient with auricular fibrillation who has no heart failure, but who has been fibrillating for, let us say, a year, you would not hesitate to use quinidine to restore a normal rhythm in the hope that as a result the patient might feel better? You would do that in the face of the danger of occasional emboli resulting from the restoration of a normal rhythm?

Dr Pardee Certainly If the patient came under my care for the first time and I knew that the fibrillation had been present for a year or two, and if he had not had serious failure, I would think it was worth while to try quinidine to see whether or not normal rhythm could be resumed

Dr Gold If you give enough quinidine you will restore normal rhythm in about 95 per cent, so that your result is pretty secure

Dr Pardee About two thirds of those patients in my experience hold their normal rhythm for a long enough time to make it worth while

Dr Gold As I see it, you agree that there is a risk of embolus, but you believe it isn't great, and the benefits of restoring normal rhythm in these cases justify taking the risk

Dr Stewart I think it might be well to call attention to a recent paper in the *Journal of the American Medical Association* describing a patient who had repeated showers of emboli These kept up for months Realizing that something sinister might happen, it was nevertheless decided to give the patient quinidine Normal

rhythm was restored and the patient had no more emboli.

DR. PARDEE: I had just such a case, in which quinidine was given for that reason. This woman had been having emboli for periods of months and it seemed worth while to attempt to restore normal rhythm to overcome blood stagnation in the auricular appendages. This was successful and she did not have any more emboli until two or three years later, when she again had auricular fibrillation.

I have never been quite satisfied that the change from auricular fibrillation to sinus rhythm was a major cause for the dislodgment of thrombi.

DR. GOLD: I had an experience which was the opposite of Dr. Pardee's. This was a young woman with rheumatic heart disease with mitral stenosis and very slight cardiac enlargement. She had been fibrillating for only a few weeks and the irregular pounding of the heart was annoying to her. After a dose of 15 grains of quinidine per day for three days the rhythm returned to normal. She had enjoyed the normal rhythm only four hours when an embolus passed to the brain. Within the next two days there were three more and, on the fourth day after the treatment was started, she was dead. Mind you, she wasn't getting on very badly with the fibrillation. It was at most only a source of annoyance.

DR. MCKEEN CATTELL: Dr. Eggleston, Dr. Randall is here. He is professor of therapeutics at the University of Texas. Could he be asked to comment on that?

DR. EGGLESTON: Conditions may be very different in Texas. Let us hear what the reactions are.

DR. EDWARD RANDALL: I should like to ask Dr. Pardee how much importance he attaches to the auricular fibrillation in a person who gets along reasonably well, having compensated for his fibrillation?

DR. PARDEE: A patient may lead a very satisfactory and relatively symptom-free life with properly treated auricular fibrillation. I agree to that. When a person has been doing that for many years, or for at least two years, since Dr. Eggleston suggested that period, it would seem to be perhaps not worth while to put him through a course of quinidine just to enable him to stop taking digitalis, because that is all you would be accomplishing.

DR. RANDALL: In other words, let well enough alone.

DR. PARDEE: However, in the type of case I have already discussed, quinidine should be used, and my experience with it has been good enough. In all of my private and hospital experience I have seen but one fatality. So I think it occurs rarely.

DR. DEITRICK: It is my impression that, if one weighs the criteria for selection carefully, suitable candidates for quinidine are rare even with those who have a large experience.

DR. EGGLESTON: There is a group of auricular fibrillators of the paroxysmal type that are troubled often during their paroxysms of fibrillation by considerable discomfort, who occasionally manifest symptoms of congestive heart failure during the attack of fibrillation. In that group the paroxysms ordinarily are relatively short in duration, varying from a few beats to a maximum of several days. I wish we had the time to discuss these, but we should pass on to matters of dosage.

Dr. Stewart, what is your plan of dosage of quinidine, if you have one?

DR. GOLD: Do you mean for the purpose of abolishing the attack of auricular fibrillation, or to prevent a recurrence?

DR. EGGLESTON: To abolish the attack of auricular fibrillation and maintain sinus rhythm, if you use it that way.

DR. STEWART: For auricular fibrillation, we first give the patient 0.2 Gm. by mouth and maybe two hours later repeat the dose, to see whether there is any idiosyncrasy. If there has been no indication of idiosyncrasy, I think one might then give the therapeutic amounts.

DR. EGGLESTON: What are they, please?

DR. STEWART: A dose of 0.4 Gm. at four-hour intervals.

DR. EGGLESTON: Continually day and night, or day only?

DR. STEWART: First I would give about four doses the first day.

DR. EGGLESTON: None at night?

DR. STEWART: No, I would stop during the night. I would give five doses the second day, and perhaps six the third day.

DR. EGGLESTON: When you get up to five or six doses do you give one or two during the night in your practice?

DR. STEWART: Yes.

DR. EGGLESTON: I raise the question as to whether you should give any of the doses at night, because of the fairly rapid elimination of quinidine and the fact that the action of quinidine appears to depend to a certain extent upon the concentration in which it is present in the blood stream.

DR. STEWART: That is why I start over every day.

DR. EGGLESTON: Dr. Pardee, what is your practice?

DR. PARDEE: I have usually given an initial dose of 0.2 Gm. as a test dose, but only one such

dose; following that I have given 0.4 Gm. at four-hour intervals for the first day, with one dose at night.

DR. EGGLESTON: You introduce a night dose even on the four-hour interval schedule?

DR. PARDEE: The next day the same schedule is followed. If that is not successful, I shorten the interval between doses to three hours, with two doses at night.

DR. EGGLESTON: What is your practice, Doctor?

DR. RANDALL: I do not give more than 1 to 1.5 Gm. in twenty-four hours.

DR. EGGLESTON: Irrespective of the patient's failure to respond?

DR. RANDALL: Yes.

DR. EGGLESTON: Dr. Gold, I think you have some very definite ideas on the subject of dosage of quinidine.

DR. GOLD: We should distinguish between abolishing an attack of auricular fibrillation and preventing a recurrence. The problems are different. Let us speak of dosage for abolishing the attack. The size of the single dose and the interval between doses depend in part on how ill the patient is. If one judges that the attack is causing serious trouble the dose should be larger and the interval shorter in order to terminate the attack as quickly as possible. In most cases I don't awaken patients for night doses. My usual plan is to give 0.3 Gm., or 5 grains, every two hours until the fibrillation ceases, or throughout the day. If the fibrillation does not come to an end that day, the dose is doubled the next day, and pursued in the same manner. It is rare that such doses fail, and they are without danger because the plan is interrupted when fibrillation ceases or minor toxic effects appear, such as buzzing in the ears or clouding of vision.

DR. PARDEE: Or diarrhea.

DR. DEITRICK: May I ask how many patients Dr. Gold has seen who require 2 Gm. or 3 Gm. a day in order to get the effect?

DR. EGGLESTON: I don't know how many he has seen, but I have seen several.

DR. GOLD: I would say that in many of them, fibrillation goes after a gram or two is given in this way. I should add that I don't often use it for long-standing fibrillators, but only in those of recent origin. I should also add that for preventing attacks we often need larger doses, sometimes as high as 3 or 4 Gm. a day. I assume this is so because of the force of the stimulus, emotional or otherwise, at work in the life experiences of the average ambulant patient, which may at times break through the effects of small doses.

The system for the case of paroxysmal fibrillation which I usually pursue in order to prevent recurrences is to give one dose of 0.3 Gm. (5 grains) three times daily until there is an attack. The dose is then raised by 0.3 Gm. (5 grains) per day until there is another attack. The dose continues to be raised from a level of 15 to 30 to 35 or more grains a day until a level is attained at which attacks no longer occur, or minor toxic effects preclude its further use. Raising the daily amount is carried out by shortening intervals between the single doses and then if necessary by increasing the size of the single doses. It may take some time to attain the appropriate level of dosage, but it is safe and sure. Special cases require special modifications.

DR. C. H. WHEELER: How many doses of 0.6 Gm. would you be willing to give in the same twenty-four-hour period? You said every two hours. You mean twelve doses? When do you stop?

DR. GOLD: I have given as many as nine doses of 0.6 Gm. (10 grains) each in this way. Our system of dosage has its own safety controls. It calls for discontinuing the dose when the therapeutic objective—namely, normal rhythm—is attained, or if minor toxic effects appear. If one follows this system, there are few therapeutic failures, and no disasters.

DR. PARDEE: Don't your patients frequently have gastrointestinal symptoms from those doses?

DR. GOLD: Yes, at about 60 grains, or 4 Gm. a day, gastrointestinal symptoms are fairly frequent. Some patients are so sensitive that gastrointestinal symptoms, cramps and diarrhea, occur with the first 0.6 Gm. dose.

DR. EGGLESTON: You find that in the paroxysmal type of fibrillation you require larger total doses than are commonly used for maintenance?

DR. GOLD: Yes, for the protection of the paroxysmal fibrillator against recurrences, rather large doses are usually needed.

DR. STEWART: Dr. Eggleston, it is not the general practice for cardiologists to use the larger doses of quinidine, which Dr. Gold advocates, because of what we think are real dangers in the use of the drug. I think that the students should not be left with the impression that it is the consensus that such large doses should be given or that the drug can be given with the freedom which they might have inferred from Dr. Gold's statement.

DR. GOLD: To avoid misunderstanding, I should add that the doses which I have recommended for the average patient are no larger than those of others. Dr. Stewart has just advocated as high as 2.4 Gm. a day for abolishing an attack, and my plan calls for a very little more the first day. I recommended starting with only 1 Gm. a day and increasing the dosage if necessary for preventing recurrences. I have gone further and

applied a principle which is applicable to a great many drugs if the usual range of dosage fails to produce effects—namely, to continue its administration in increasing amounts until either the therapeutic effects appear or minor toxic symptoms preclude its further administration. I know of no experience with quinidine which makes this procedure inapplicable. As to the very large doses, I have merely indicated that on occasions they are necessary and have pointed out the system by which they may be given with safety.

You may be interested in the experience of S. A. Levine, of Boston, who states that he believes he saved a life in a patient with ventricular tachycardia with a dose of 1.5 Gm. repeated five times a day for several days, when smaller doses were ineffectual.

DR. WHEELER: Dr. Eggleston, I should like to ask whether anyone here has ever seen anything that made him glad that he had given the small test dose of quinidine? When we give quinidine, we don't give a test dose. We do as we do in treating malaria now; we give an initial dose of 0.9 Gm.

DR. EGGLESTON: I am very glad you brought that up. Although I still adhere to the old practice of giving a test dose, I am not convinced in my own mind that it serves any useful purpose.

DR. WHEELER: Has anybody had any experience with that?

DR. STEWART: I have never found any toxic effects from the preliminary dose.

DR. PARDEE: The only interesting thing that dose has ever done in my experience is to stop the auricular fibrillation.

DR. GOLD: I don't think that a test dose ever leads to a change in the course of therapy with quinidine, except for the occasional experience mentioned by Dr. Pardee that it may suffice to terminate the attack. As a means of detecting hypersensitive people and thus protect against poisoning, it seems to be of no value.

DR. WHEELER: But you still do it?

DR. GOLD: No, I don't do it. I never did.

DR. WERNER: Dr. Pardee, I should like to ask whether, in those cases you mentioned in which fibrillation was terminated and normal rhythm was maintained for a year, a so-called maintenance dose was used?

DR. PARDEE: I always stop the quinidine a day or two after normal rhythm is resumed. I think the continued administration is bad for the heart.

DR. EGGLESTON: Do you think that is so in paroxysmal fibrillators who are subject to very frequent paroxysms?

DR. PARDEE: You have to balance factors and take the lesser of two evils.

DR. EGGLESTON: And if the fibrillation were the worse of the two evils?

DR. PARDEE: You always have to bear in mind that there is another method of treating auricular fibrillation, which is the administration of digitalis. It is not so harmful a drug as quinidine in the long run, if properly given.

DR. EGGLESTON: In the event that in a given patient digitalis does not abolish the recurrences do you then ration your patient with quinidine?

DR. PARDEE: Such a case might occur. I have not seen one.

DR. GOLD: I am not at all impressed with the danger of continued use of quinidine in doses sufficient to prevent recurrences.

STUDENT: Dr. Eggleston, I should like to ask whether one could use quinine, if no quinidine were available, and treat with that instead of the quinidine?

DR. EGGLESTON: Dr. Stewart, what do you think about that?

DR. STEWART: As you mentioned historically a few moments ago, quinine was first used for restoring the normal rhythm. That is how this whole business started.

DR. EGGLESTON: Quinine can be used in the absence of quinidine, but it is not as effective in the control of auricular fibrillation, according to all the experience and investigations.

DR. WALTER MODELL: I want to say that if a case of idiosyncrasy is ever discovered with the first dose of quinidine, one might use quinine, because it is an optical isomer of quinidine, and idiosyncrasy for one does not apply to its isomer.

DR. EGGLESTON: You spoke at the very beginning of the use of quinidine in ventricular tachycardia.

DR. DEITRICK: Yes.

DR. EGGLESTON: Would you tell us how you use it?

DR. DEITRICK: From my experience at the hospital, this is the best use for quinidine. I would have no hesitancy in giving it to a patient who has just suffered coronary occlusion. The tachycardia interferes seriously with the heart's action.

DR. EGGLESTON: You tend to subscribe to the idea, proposed from Boston, of the prophylactic use of quinidine in patients with acute coronary occlusion, or do you not?

DR. DEITRICK: No, I do not.

DR. EGGLESTON: You would wait until the tachycardia makes its appearance?

DR. DEITRICK: Yes, as a rule I do.

DR. GOLD: I think it is wise to start the drug if premature ventricular contractions occur, especially if they are frequent, in the course of coronary occlusion. They sometimes presage ventricular tachycardia.

DR. DEITRICK: I might also do so in some cases.

DR. EGGLESTON: How do you feel about that, Doctor?

DR. RANDALL: I do not use it prophylactically as recommended.

DR. PARDEE: In cases with ectopic beats of ventricular origin, I would give it. I would like to ask Dr. Gold to express his opinion about the use of atropine instead of quinidine in such cases. A recent work has suggested that large doses of atropine may have a more powerful protective action against the onset of ventricular tachycardia.

DR. GOLD: I know about the work, but have no experience with it.

DR. CATTELL: It is purely experimental in dogs.

DR. PARDEE: Yes, but it was very good for the dogs. I use quinidine, but I would like to use atropine because I don't think it has such a bad effect upon the myocardium.

DR. EGGLESTON: Would you use the quinidine routinely in coronary thrombosis?

DR. PARDEE: Not routinely, only after the appearance of numerous premature beats.

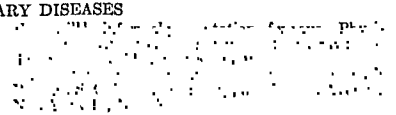
DR. EGGELSTON: What dosage would you use under those circumstances?

DR. PARDEE: About 0.4 Gm. four times a day.

DR. EGGELSTON: About the same as for control of fibrillation.

INTERN: Is the dose the same for auricular paroxysmal tachycardia?

DR. EGGLESTON: Yes. Either I am very slow in bringing out the various points or we have gotten too interested. But the time has passed and I have to declare the hour over. I wish we could go on because there are a good many points which still ought to be mentioned and discussed.



Summary

DR. GOLD: It is difficult to summarize today's conference without repeating it, because of the many phases of the subject of quinidine which were discussed. In what conditions is it especially useful or essential? When quinidine restores a normal rhythm in a patient with auricular fibrillation, how serious is the danger of embolus? Should one attempt to restore normal rhythm in long-standing auricular fibrillation? By what criteria are patients with auricular fibrillation selected as candidates for quinidine treatment? Is there value or danger in the prolonged use of quinidine to prevent recurrences of auricular fibrillation in those with repeated paroxysms? Should quinidine be used routinely to prevent ventricular tachycardia in acute coronary thrombosis? If not, when is it applicable in these cases? Should digitalis and quinidine be used at the same time? Is there value or danger in such practice? These are some of the major questions which were explored in the conference.

Quinidine is an important drug. Its chief value in heart disease is for the control of disorders of cardiac rhythm, not primarily for problems of heart failure. Its most important use is the treatment of ventricular tachycardia, usually an urgent condition in the course of coronary thrombosis. It has use in some cases of auricular fibrillation, flutter, auricular paroxysmal tachycardia, and premature contractions. About these matters agreement seems to be fairly complete. Concerning other details, experiences have differed and reactions to them are variously shaded. Their discussion has supplied a large part of the interest of this conference. Several plans of quinidine dosage to meet various situations have also been presented.

CLINICAL SESSION ON CHRONIC PULMONARY DISEASES

The thirty-fourth Clinical Session on Chronic Pulmonary Diseases, under the auspices of the Tuberculosis Sanatorium Conference of Metropolitan New York, will be held January 10 in the Amphitheater at Cornell University Medical College, 1300 York Avenue, New York. From 7:45 to 8:30 P.M.

NATIONAL PUBLIC HEALTH NURSING DAY

The first National Public Health Nursing Day will be held throughout the country on January 26. The theme of the observance will be "Know Your Public Health Nurse—Who She Is, What She Does." In charge of details is the National Organization for Public Health Nursing, Inc., 1790 Broadway, New York 19, New York.—*J.A.M.A., Nov. 25, 1944*

Special Article

MEDICAL ASPECTS OF JUVENILE DELINQUENCY

ALOYSIUS S. CHURCH, M.D., Lincolndale, New York

AT THE present time the problem of juvenile delinquency is being considered by every type of social agency. Sociologists, teachers, and social workers are accepting the challenge in terms of newer lights thrown on the subject by Child Guidance Clinics. As for the physician, he has concerned himself primarily with the relationship of body to mind and he offers a long record of achievements, especially in maintaining the child's physical organization and permitting the child to survive despite his exposure to virulent and dangerous organisms. It is true that the physician has been labeled somatic-minded, especially with regard to treatment of behavior disorders from the point of view of "infections" or "gland trouble." However, the error of this approach to conduct is no different than that of Watson's, whose behavioristic recipe eliminates the concept of consciousness.

Fortunately, the tonsil and redundant prepuce are not being blamed so much for the child's incivility, surliness, or paradoxically, in some cases, for the child's domesticity, and in others, for his unsociability. Focal infections and abscessed teeth are also taking less blame for aggressiveness and stealing. The physician of today is returning rapidly to the hylomorphic concept, proclaiming man one complete substance, and considering him a body and mind, not accidentally related, but a unified being.

It is strange how this concept, which enjoyed survival from as far back as Plato, became almost completely obliterated by the influence of one man, Descartes, a sixteenth-century philosopher, who propounded the doctrine of psychophysical parallelism, dividing man into two units, body and mind. Since his time, physicians have been victimized by the dichotomy and even in this day, despite the important works of Pavlov,[1] Wolf and Wolff,[2] Crile,[3] and Cannon,[4] the dualistic philosophy has given basis to many practices in the field of medicine.

In the treatment of children who are either rebellious, antisocially aggressive, or socially or vocationally inhibited, psychosomatics brings the problem directly to the physician. In other words, misbehavior is not dissociated from the total child and biologic functioning. Stealing, lying, truancy, disobedience are expressions of a faulty biologic adjustment and fall into the province of the physician. In juvenile delinquency the total child is having difficulty in finding the meeting point of his instinctive needs on one hand, and the laws of God and society on the other. This may be caused primarily, but not solely, by intrapsychic pathology, but always involving the total child as a psychosomatic unity.

In an unprecedented article of 1941 Dr. Vogel[5] discusses delinquency as a medical problem. He gives delinquency the same status as a public health officer gives typhoid fever or diphtheria. "Are not such problems as tantrums, extreme shyness, troublesome aggressiveness, pathologic lying, or stealing in children, matters that concern human welfare, and are they not evidences of levels of health?" The article is a plea for a medical program to reduce divorces, suicides, crime, and juvenile delinquency.

Clinical Observations

1. Malnutrition.—The new science of nutrition has stressed the importance of diet qualitatively and quantitatively. The biologic importance of vitamins has been grossly exaggerated, but this does not mean that they should not be used, especially with children. It is doubtful if vitamins are potentially capable of improving intelligence, as is often claimed, but there is sufficient literature recording significant experimentation with vitamin B. Irritability, moodiness, lack of cooperation, and "meanness" are listed as symptoms of slight vitamin B deficiency by several writers.[6, 7] With more severe vitamin B deficiencies such mental states as apathy, depression, and emotional instability have been observed. The use of vitamin B complex is indicated to supplement a well-balanced diet in delinquent children, especially if they give a history of anxiety, irregular meals, home conditions not conducive to healthful ingestion or digestion, and improper constituency of meals qualitatively, quantitatively, or both.

The delinquent child offers several interesting and significant problems under the heading of nutrition, especially if the problem is related to more primary causative factors of the child's misconduct. These are:

1. Parental rejection (often on unconscious levels)
2. Parental neglect

Clinical Director, Lincoln Hall, Lincolndale, New York.

3 Parental hostilities (not infrequently accompanied by wishing starvation for the child)
4 Parental ignorance
5 Cultural patterns passed on from generation to generation, or neighbor to neighbor Certain races incline specifically to a high carbohydrate diet, devoid of vitamins B and C
6 Inability to prepare vegetables to preserve their nutrient value or inability to prepare the vegetables to entice the child
7 Ineffectuality of parents, which is a frequent finding in case studies of delinquent children Such parents, or parent-substitutes, are unable to supervise a child's diet

Of 750 children admitted to an institution for delinquent boys, ranging in age from 11 to 17, 80 per cent showed evidences of undernutrition or malnutrition in various degrees This is an important finding and must be related to the significance which Freud gave the mouth, especially with reference to stealing, etc Those who live with delinquent children often relate various manifestations of oral deprivation Most delinquent children crave food, steal money for it, and ingest it rapidly They hide food in institutions even when they are assured of 'three squares" They talk about food as much as, if not more than they do about 'Superman" The delinquent child's mode of ingestion leads to a peculiarly high figure for abdominal complaints, and is closely linked to the high incidence of insecurity, tension, restlessness, and for the most part, a need for affection Food represents love and survival for the child

The question of transient hypoglycemic states is a very pertinent one The mode of the delinquent child's life is conducive to episodic or chronic anxiety states Many delinquent children steal and are antisocial because they have experienced hostility from their fathers A child who was beaten by his father at regular intervals, and who was committed to an institution for absconding from home, told of his constant hunger and his ability to satisfy his appetite 'only with lots of candy"

The study of 50 boys admitted to an institution for delinquent children in the first three months of 1943 was made on an informal basis, to determine what they ate at home Some came home for meals but occasionally Many ate at drug-store counters, hamburger stands, and the like Still others, who ate at home, partook of the most discrepant diet imaginable Of these 50, approximately 50 per cent were underweight by more than fifteen pounds, and 80 per cent showed pallor, poor muscle tone, and signs of vitamin A, B, and C deficiency In all cases there was evidence of malnutrition which was easily related to other factors causative of delinquent behavior The insecurity which goes along with hunger may motivate behavior not socially acceptable

In the field of delinquency there is a need for wider acceptance of the fact that to some extent human conduct has its roots in protoplasmic substance, the constituency of which depends upon the nutriments assimilated

2 Sensory Defects—Impaired vision and hearing probably play a greater part in the cause of delinquent behavior than can be statistically substantiated Sense deprivation has a profound influence on the personality and may lay a groundwork for social maladjustment Truancy, as any other delinquent behavior, has a multiple causality, but impaired sensory acuity is closely related to it In one study, 69 per cent of poor readers were found to suffer from incoordination of the ocular muscles Forty-five per cent had low fusion, i e , the image from each eye was not properly blended into a good picture The incidence of poor readers among delinquents is high Blanchard[8] clearly illustrates the relationship between truancy and reading disabilities, and other writers as well attest to the significant bearing of truancy on serious delinquent behavior A poor reader may suffer from laterality, mixed dominance or reversals [9] Witty and Kopel[10] discuss vision as related to personal adjustment Muscle imbalance and fusion difficulty are emphasized in their book "Being free of refractive error does not mean freedom from visual defect" "Muscle imbalance, fusion irregularity, poor depth-perception, deficient acuity, astigmatism, apparently are found with equal and high incidence"

In discussing hearing impairments, a recent quotation from a talk given by Helen Keller strikes home "I consider my deafness to have been much more a serious handicap than my blindness" The implications of this statement are many and serious, and the literature abounds with testimony to the effect that partially deaf persons often manifest withdrawal or aggressiveness Delinquency may find its soil in deafness if not cared for properly or detected early enough Solomon[11] makes a plea for the understanding of the emotional problems of the deaf There is a need for audiometric tests and a still greater need for complete management of the child sufferer and his parents and teachers

3 Endocrine Disorders—Volumes have been written on the subject of the endocrine secretions as potential determinants of human conduct In the field of delinquency, physical immaturity is frequently encountered, and often the concomitant behavior is not compatible with the chronologic age, undoubtedly this is one of the important factors to be considered in the treat

ment or prevention of delinquency. This immaturity is in many cases related to other factors, more particularly, parental rejection or negligence. More and more evidence is forthcoming daily to show positive correlation of physical growth and efficient physiologic functioning with parental love and familial security. Case studies of delinquents reveal that they do not have their affectional needs met. There is indication that the glandular inadequacies do not account for only the physical maldevelopment but also for the decrease in ability of the child to cope with life. The responses of the delinquent are often infantile and immature, and hormonal inadequacy states may stand investigation as possible influences retarding the child's competency and efficacy to deal with the realities.

The mental problems of puberty have been studied[12] and related to "a sense of frustration, defeat, and personality difficulties which often arise from the confused and conflicting neighborhood and family life" of adolescents and preadolescents. Hypogonadism, delayed puberty, cryptorchidism, eunuchoidism must be considered as related to behavior, and delinquent children given more detailed scrutiny especially in terms of the hormonal status. The questions to be asked are: Is the child's state one of insufficiency, and consequent psychic overcompensation? Are his biologic drives augmented or abated by his hormonal situation? Is it directly or indirectly related to the behavior which has become personally or socially problematic? Alexis Carrel made a statement in his recent book which points to this:[13] "No eunuch has ever become a great philosopher, a great scientist, or even a great criminal."

4. Cardiac and Other Disabling Diseases.—With the increase in incidence of rheumatic fever, the cardiac child is encountered in any group of delinquents. In 750 boys, ages 11 to 17, it was estimated that approximately 10 per cent had a history or showed signs or symptoms of cardiac disease. As the cases were surveyed, it became obvious that illnesses of long duration and disabilities play a part in truancy and aggressive behavior. Continuity of school is often interrupted. Fatiguability may lead to overcompensatory attitudes. Such children may suffer anxieties and fears. Long confinement in hospitals and homes often leads to preoccupations not always of the healthful variety. The cardiac child may have a lot of anxiety about his pallor, failure to gain weight, repeated nose bleeds, palpitation, and fatiguability. This anxiety is aggravated in a home with persons who do not give the child security and affection. Boys often find this security and love on the street or in the alleys.

Not infrequently mishaps occur with children suffering from St. Vitus' Dance. They are called disobedient because they do not stand still, are inattentive, or because their "minds wander." In a few selected cases the chorea was of a mild nature, but sufficient to disturb the relationships between pupil and teacher or child and parent.

Much could be offered the child in management and interpretation to parents, especially to those who do not know how to cope with long illnesses. Convalescence management requires consideration of the child's abilities and wishes. Children long confined to bed need not spend long hours in harmful preoccupation. Bibliotherapy and hobbies are in order as part of the treatment. Parental attitudes need to be studied to avoid causing a greater rift between parent and child, good relationships between whom help in the formation of sound social concepts.

5. Deformities.—The attitude of a child toward his deformity can be managed by parent and physician. Parents often need insight into their own attitudes toward the deformity of the child, especially if the child is born with it. If it is acquired, the physician may more easily guide the parents. Crippled and deformed children suffer from feelings of inferiority, low self-esteem, feelings of envy, and suspiciousness, and may withdraw to be asocial or become excessively aggressive. Often their relationships with parents are disturbed by parental rejection, and this lays a groundwork for later poor social relationships. The deformity need not be of a gross nature to be disturbing. Spectacular changes were noted in two boys who had their squint corrected for cosmetic purposes only. Dental replacements, especially of the central teeth, helped several boys to become social beings. The treatment of acne is indicated in all cases. A maldeveloped arm of a boy known as "the claw" appeared, after study of his case, to be the prime factor in his antisocial ideation. Referral to an agency where vocational guidance was offered proved to be helpful.

The problem resolves itself to the management of the whole child and not only his deformity. Some children can "take it," and others cannot. Some may grow normally and socially stronger with a handicap, but studies would show (if they grew stronger) that their deformity was treated in an affectionate setting, and with wise guidance.

6. Epilepsy.—That personality disorders occur in epilepsy is well objectified in abundant literature. Between 1914 and 1933, LaPierce Clark wrote prolifically on this subject. Today the concept of epileptic personality has been given a valid status in the list of medical diagnoses. "Eccentricity, supersensitiveness, emotional poverty, rigidity" are listed as the out-

standing traits of the epileptic personality Children with such traits become turbulent, argumentative, quarrelsome, resent correction, and show stubbornness The epileptic child is as concerned about his ego as is the psychoneurotic about his body. Some writers put it very plainly, "bad behavior is a seizure," and to be sure there are many more epileptic personalities than was formerly known The electroencephalograph is now a distinct help to the physician

It is interesting to note that children suffering from migraine show more socially acceptable behavior They are pleasant, well-mannered, obedient, shy, etc [14]

7. *Postencephalitic Behavior*.—Of all diseases known to produce alterations of behavior, encephalitis has received the most attention The antisocial quality of this behavior has given it a valid and significant place in the study of delinquency. Postencephalitic behavior is said to be characterized by exaggeration of the instincts and of the appetites There is a tendency to be overactive. Most writers record an inability of the patient to inhibit activity [15] The history of the delinquent child, if related accurately, may well throw light on the diagnosis of a behavior problem, especially if the child suffered a persistent high temperature with one of the infectious diseases, or if the mastoid cells were involved.

Summary and Conclusions

The material herein presented is derived from clinical observations which did not lend themselves to statistical presentation, and does not constitute a complete study or survey of literature in the field of medical possibilities in the prevention and treatment of delinquent behavior Such a study of necessity would have to include prenatal care, the process of birth, etc , and give special emphasis to the experience of the orifices in infancy and childhood. The physician's participation in the feeding process and toilet activities gives him an excellent opportunity to lay foundations for sound social concepts later in life Delinquency is a disorder of social adaptation, and as such it has roots in the early relationships with the mother or mother substitute

If such a relationship is one of love, the chances for antisocial attitudes are lessened The physician's task is one of not only preserving biologic structures and functions but also of giving them the sacredness and relationship to the total child and his environment The physician must, by virtue of his training and experience with life processes, be ever concerned about the biologic drives, and their relationship to cultural patterns of life Human relationships, especially those deeply biologic, must be respected and nurtured, maintained, and sustained

Problem children require tedious study, and an attempt should be made to restore the child's total person In the realm of nutrition alone, the physician could contribute effectively In hypoplastic states, all endocrinologic possibilities should be studied In puberal evolution, sex education by the physician or instructed parent would simplify the adolescent's life and permit a more efficient growth Shaming of masturbation should be condemned by physicians. Children should not associate shame or terror with genital functions Children in long convalescence should be supervised to avoid unhealthy preoccupations, and to be given guidance to help them live with their limitations Deformities should be corrected if this is at all possible If not, the parent should be instructed to guide the child into a suitable vocation More detailed examination of the eyes and ears may bring to focus a defect falling within possibilities of correction, and thus removing factors often causative of maladjustment in the school The electroencephalograph should be utilized to discover any cortical dysrhythmias Detailed medical histories may bring to light the possibility of encephalitis, and alter treatment plans for the "bad child"

All told, the chief ingredient of any medical treatment of problem children is love of children to such a degree that it will educe love from children's parents and keepers

To be most effective in combating delinquency, the physician becomes a member of a team, working closely, consisting of the parent, teacher, social worker, nurse, psychologist, and psychiatrist In this way the whole child will be studied and treated

Case Report

LANATOSID-C

Clinical Experiences with Selected Cardiac Cases*

BERNARD M. SCHOLDER, LT. COMDR., MC(S), USNR

THE isolation in recent years of crystalline digitalis glycosides has marked a distinct advance in digitalis therapy. The variations in potency of different digitalis products used in man have been stressed by other workers.[1] These experiences have stimulated interest in the use of crystalline preparations which can be standardized gravimetrically and hence do away with the necessity of bio-assay.

Lanatosid-C (marketed under the name of cedilanid†) is a pure crystalline glycoside obtained from Digitalis lanata. It has been investigated sufficiently[2-8] to show that it is pharmacologically active and clinically safe. Reports are also available which indicate its clinical behavior.

Fahr and LaDue[2] stated: "Our results indicate that this drug should now have wide clinical trial so that we may be fully informed as to its advantages over the usually employed purpurea preparations." With a view to extending clinical observations the present study was undertaken in May, 1941. The report herein submitted deals with purely clinical studies made on a group of patients selected from clinics, wards, and private practice. The indications for the use of this product were the same as those for digitalis purpurea. No attempt was made to run "controls." Rather was it desired to administer the drug in the same manner as digitalis purpurea would have been and "see how it works." The patients selected were, therefore, those who were not receiving any digitalis at the time of the first observation, or those whose response to digitalis purpurea was not satisfactory.

Classification of Patients

The patients followed during the period from May 1941, to May, 1943, fell into the following categories:

A.	Cause	
	1. Hypertension	19
	2. Arteriosclerosis	5
	3. Rheumatism	14
	4. Unknown	1
B.	Rhythm	
	1. Auricular fibrillation	21
	2. Normal sinus rhythm	16
	3. Auricular flutter	1
	4. Auriculoventricular nodal rhythm	1
C.	Functional	
	Class II	20
	Class III	5
	Class IV	14
D.	Ages	
	11–20	1
	21–30	2
	31–40	6
	41–50	5
	51–60	8
	61–70	6
	71–80	8
	81–90	3
E.	Sex	
	1. Female	30
	2. Male	9

Case Reports

Case 1.—The following case demonstrates the efficiency of the drug when used intravenously: A. S., a white woman of 29, had rheumatic heart disease with superimposed subacute bacterial endocarditis. On September 24, 1941, at 11:30 A.M., one hour after a blood transfusion, she complained of shortness of breath and tightness in the chest, relieved by elevation of the head. At 4:00 P.M. she again complained of tightness in the chest and a choking sensation. At 4:15 P.M. her pulse was imperceptible, the ventricular rate was 160 to 180 and irregular; the blood pressure was not obtained; there was marked pallor and cyanosis of the nails and lips; she was given oxygen, carotid sinus pressure, 1 cat unit of digitalis purpurea intramuscularly, without effect on the ventricular rate. Table 1 shows patient's response to intravenous injection of the medication.

FIG. 2. [illegible] Follow-up was not [illegible] restored.

Case 2.—The following case illustrates the effects in auricular fibrillation: G. B., a 58-year-old woman, had hypertensive heart disease with auricular fibrillation of four years' duration; she had had several episodes of congestive failure. She was kept on digitalis purpurea, 1 cat unit daily. During four months before the first observation the congestive heart failure increased; digitalis purpurea was increased to 3 cat units daily; she was also given ammonium chloride and injections of salyrgan-theophylline. She was first seen on March 9; she was admitted to the hospital with dyspnea, cyanosis, peripheral edem[illegible] [illegible] [illegible] [

was possible to make several experiments during a two-year period of observation of this patient. From May, 1941, to September, 1941, both cedilanid and ammonium nitrate were discontinued at different periods; with both medications discontinuation was followed by an increase in weight, rate, and size of the liver. Then from September, 1941, to March, 1942, the patient was kept stabilized on 1.5 mg. of cedilanid and 4 Gm. of ammonium nitrate daily. When cedilanid was discontinued the weight, ventricular rate, and liver size increased. On resumption of cedilanid weight, rate, and liver size were reduced. The patient was stabilized again for a period of two months, cedilanid was discontinued, and there was again an increase in weight, rate, and size of liver. When cedilanid was resumed there was a return of the figures to previous levels. These repeated observations demonstrate the efficacy of the drug in a case of normal sinus rhythm.

Case 4.—This case illustrates the effect of the drug in paroxysmal fibrillation. F. H., a 65-year-old woman, had hypertensive heart disease. She was first seen on March 30,1943, at 4:30 P.M. with auricular fibrillation and a ventricular rate of 140. The exact onset was not determined, but from the history it was assumed to have occurred three to four days before the first observation. Cedilanid, 0.4 mg., was given intravenously. Within ten minutes the rate dropped to 120; at 7:30 P.M. the ventricular rate was 100; 1.5 mg. of cedilanid was then given by mouth. The next day the auricular fibrillation persisted with a ventricular rate ranging around 90, and the patient was given 2.0 mg. of cedilanid by mouth during the day. On April 1 at 3:30 P.M. normal sinus rhythm was restored and on this day an additional dose of 1.5 mg. had been administered. In this patient a total of 5.4 mg. was given in forty-eight hours. The patient maintained sinus rhythm until May 1, 1943; at 2:00 A.M. she was awakened by pain in the chest and a choking sensation which lasted until 11:00 A.M.; it returned again at 2:15 P.M. and remained severe for about two hours. On May 3 pain recurred twice during the day. On May 4 the patient was seen at 5:45 P.M. with auricular fibrillation and ventricular rate of 120 and marked pulse deficit; at 5:55 P. M. 0.8 mg. of cedilanid was given intravenously; at 6:05 P.M. the ventricular rate was 110; at 6:10 P.M. the ventricular rate was 96; at 8:15 P.M. auricular fibrillation was present, the ventricular rate was 84, there was no pulse deficit. At 11:00 P.M. her condition was the same; the patient was given 1.0 mg. of cedilanid by mouth. On May 5, at 2:00 P.M. auricular fibrillation was 96, there was no pulse deficit, and slight nausea was present; she was given 1.0 mg. of cedilanid by mouth. On May 6, 1:30 P.M., the ventricular rate was 72, slight nausea occurred, and cedilanid was discontinued. On May 10 there was auricular fibrillation, the ventricular rate was 90, and there was no nausea; cedilanid was resumed, 1.0 mg. daily. On May 19 the patient had normal sinus rhythm, ventricular rate of 70, no nausea, and was feeling very well. The first attack, lasting five to six days, was brought under control within forty-eight hours. The second more persistent attack lasted nineteen days, during which time the ventricular rate was well controlled by cedilanid with the eventual restoration of sinus rhythm.

Case 5.—J. C., an 84-year-old man, had arteriosclerotic heart disease; he was first seen on May 8, 1943, complaining of cough, discomfort in his chest, cyanosis of the lips, rapid ventricular rate, 150, shown by electrocardiogram to be auricular flutter with 2:1 block (Fig. 2). He was given 9.0 mg. of cedilanid from May 8 to May 11; on the latter date sinus rhythm was restored, and the ventricular rate was 68. It was not possible to obtain a follow-up electrocardiogram.

Case 6.—H. G., 45, had arteriosclerotic heart disease. Between 7:00 and 7:30 P.M. the patient noted onset of tachycardia with a feeling of faintness. He was seen at 9:45 P.M.; the ventricular rate was 188, the pulse was very small, blood pressure was 96/80, the electrocardiogram showed auriculoventricular nodal tachycardia; at 10:10 P.M. the ventricular rate was 180; 0.8 Gm. (4 cc.) of cedilanid was given i.v.; the ventricular rate was taken every five minutes. No change occurred until 10:40 P.M., when the ventricular rate was noted to be 104. The blood pressure was 110/80 and the pulse was of good quality and strong. The electrocardiogram showed sinus rhythm, which mechanism was maintained.

The following cases illustrate the results obtained in patients with auricular fibrillation:

Case 7.—M. B., a woman of 57, had rheumatic heart disease; the ventricular rate was reduced from 108 to 64 after one month on 1 mg. of cedilanid daily. This medication was discontinued because of nausea.

Case 8.—E. D., a woman of 36, had heart disease of unknown cause; the ventricular rate was unaffected after one month. The average dosage of cedilanid was 1.0 mg.; nausea developed so the drug was stopped for two weeks, then resumed gradually, but was discontinued after one month because of nausea. No reduction of rate was obtained.

Case 9.—M. G., a woman of 59, had rheumatic heart disease. 1.0 mg. of cedilanid was given daily; ventricular rate was maintained between 70 and 80.

Case 10.—L. G., a 48-year-old woman, had rheumatic heart disease. The ventricular rate was reduced from 104 to 80 after two weeks of cedilanid therapy, 1.0 mg. daily.

Case 11.—R. L., a woman of 63, had hypertensive heart disease. The ventricular rate was reduced from 90 to 64 after four months' observation by administration of 1.5 mg. of cedilanid daily.

Case 12.—H. M., a man of 52, had hypertensive heart disease, ventricular rate of 96, liver two finger-breadths below the costal margin. Medication was begun with 1.5 mg. of cedilanid daily; it was gradually increased, over a period of three months, to 3.0 mg. daily. No effect on the heart rate or liver was noted; his weight increased 8 lbs.

Case 13.—M. P., a man of 66, had arteriosclerosis. His ventricular rate was reduced from 120 to 80 by administration of 1.0 mg. of cedilanid daily, on the average, for five months.

Case 14.—H. S., a man of 32, had rheumatic heart disease. His ventricular rate was 104. No change occurred on 0.5 mg. of cedilanid daily for one month.

Case 15.—M. S., an 80-year old woman, had hypertensive heart disease, with a ventricular rate of 138 which was reduced to 80 after 12 cc. (2.4 mg.) i.v. of cedilanid; it was kept around 80 with 4 cc. (0.8 mg.) i.v. every ten days.

Case 16.—A. C., a 35-year-old woman, had rheumatic heart disease, with rapid, paroxysmal fibrillation; she was given 0.5 Gm. of digitalis purpurea orally, then 0.4 mg. cedilanid i.v.; the rate was reduced from 150 to 78 in eighteen hours.

Case 17.—M. H., a woman of 65, had hypertensive heart disease, with a ventricular rate of 100. The

rate was kept around 90 during operation for appendicitis on 0.4 mg. of cedilanid i.v.; then it remained around 100 on a postoperative dosage of 1.0 mg. daily.

Case 18.—E. R., a woman of 79, had hypertensive heart disease with a ventricular rate of 80–90; she was given 1.0 mg. of cedilanid daily.

Case 19.—M. G., a 39-year-old woman, had rheumatic heart disease with a ventricular rate of 130. She was given 7.0 mg. of cedilanid in thirty-six hours; the ventricular rate decreased to 84. Then she was given an average of 1.0 mg. daily, which

[illegible] ertensive
of cedila-
g. daily;

Case 21.—B. D., a woman of 38, had rheumatic heart disease, with paroxysmal fibrillation of 146; 0.8 mg. of cedilanid i.v. in five hours; the ventricular rate was 72 next day.

Case 22.—F. B., a woman of 49, had rheumatic heart disease. She was given 1.5 mg. of cedilanid daily. The ventricular rate was 70–80.

Case 23.—G. L., a woman of 57, had rheumatic heart disease; the ventricular rate was 100–140. six cc. of cedilanid was given i.v., then 1.0 mg. twice a day for five days. The ventricular rate dropped to 60–80.

Case 24.—J. H., a woman of 48, had rheumatic heart disease, and a ventricular rate of 120–140; headache and nausea were produced after 10.0 mg. of cedilanid was given in seven days; no reduction in ventricular rate occurred.

The following cases illustrate the results obtained in patients with normal sinus rhythm.

Case 25.—H. B., a 75-year-old woman, had hypertensive heart disease with a ventricular rate of 104; [illegible]

given 1.0 mg. of cedilanid daily. No reduction occurred after two months.

Case 27.—[illegible] ensive
heart disease [illegible] ich
increased to [illegible] of
cedilanid.

Case 29.—S. L., a 62-year-old woman, had hyper- [illegible] seen

[illegible]

disease.
She recei

Case 3
sclerosis. His ventricular rate was reduced from 70 to 58 by a dose of 1.0 mg. of cedilanid daily.

Case 31.—B. R., a man of 78, had hypertensive heart disease [illegible] He was
[illegible] veloped
[illegible] weeks.
[illegible] ensive;
[illegible] was given 1.5
with no change.
as hypertensive,

with a ventricular rate of 84. No change occurred after 1.0 mg. of cedilanid was given daily for three and a half months.

Case 34.—M. P., a woman of 30, had rheumatic heart disease, with a ventricular rate of 120. She was given 14 cc. (2.8 mg.) of cedilanid i.v. in ten hours, to no avail; the patient died.

Case 35.—M. S., a 71-year-old woman, had hypertensive heart disease, with a ventricular rate of 92; this increased to 120. She was given 1.0 to 1.5 mg. of cedilanid for four days, but she died.

Case 36.—M. M., a woman of 65, had hypertensive heart disease, with a ventricular rate of 80–100; after one week's bed rest, then 1.5 mg. of cedilanid for five days, the ventricular rate was 40–60.

Case 37.—L. M. S., a woman of 39, had hypertensive heart disease. She was given 1.0 mg. of cedilanid three times a day for three days; nausea and

[illegible]

Case 38. [illegible] heart disease with a ventricular rate of 84. His liver extended two finger-breadths below the costal margin; his weight was 184. He complained of a slight headache.

Interlobar infusion was present in the right lung with moist rales at the left base. He was given 1.0 mg. of cedilanid daily in addition to am-

[illegible]

continued because of nausea and headache.

Summary

The data herein presented illustrate the results obtained with lanatosid-C. They demonstrate that effects comparable to those which can be obtained by the use of digitalis purpurea may be expected with this drug.

Patients have been maintained for long periods without noting any side reactions peculiar to this preparation. The average oral dose has varied from 0.5 mg. to 1.5 mg. daily. Where it was found necessary to go above 1.5 mg. daily, results were not satisfactory. As much as 3.0 mg. daily for one month was given orally to one patient (Case 12—H. M.) without any deleterious effects; in another patient (Case 1—A. S.) 3.0 mg. in twenty-four hours was administered intravenously without untoward action.

In two patients with auricular fibrillation, nausea and headache occurred after the oral administration of 5.0 mg. over a seven-day period. These toxic effects were observed without a corresponding slowing of the ventricular rate. In one patient with sinus rhythm, there was nausea and headache after oral dosage of 1.5 mg. in twenty-four hours. All others tolerated the drug well.

Conclusions

It is not intended in this report to convey the impression that lanatosid-C is necessarily superior to digitalis purpurea in the results obtained; but its routine use is recommended as a *refinement* in digitalis medication.

The appeal of the crystalline glycosides of digitalis derives from the following: (1) biologic standardization is eliminated; (2) potent and dependable [illegible] absorption
[illegible] purpurea
[illegible] excessive

Correspondence

[Continued from page 44]

is 100 per cent incorrect. Reclassification was NOT carried out by the medical staffs themselves. As can be seen from the above excerpts, Blue Cross first put pressure on the hospitals. The so-called "reclassification" was then carried out by committees appointed by the hospitals, not by their staffs. Since then it has been wholly repudiated by the medical staff of the only one of the two hospitals in Niagara Falls, New York, which has the legal right to do so.

After the Niagara Falls physicians were "reclassified," as Mr. Metzger so delicately put it, subsequent utilization of Blue Cross contracts dropped to within 2 or 3 per cent of "normal," he points out. This is an attempt to make it appear that the local doctors had been responsible for alleged excessive utilization of Blue Cross contracts in Niagara Falls.

The real fact of the matter was that, from the first, Blue Cross coverage was consistently misrepresented to the public as a cut-rate contract for hospital care. Monthly payroll deductions entitled the subscriber to so many days in the hospital each year (or so he thought). Almost every subscriber had the same idea and made the same statement, "I am paying for it, so I may as well use it." That was their understanding of it. But it was not what they had bought! (Or were sold.) It wasn't insurance! When it was suggested that a survey be made to see why so many subscribers had the same misunderstanding of their coverage, this was not done. The contracts were selling well and evidently nothing was desired that would cool the public's enthusiasm. Furthermore, when excessive utilization of hospital contracts was taking place in Niagara Falls, Blue Cross was accepting the "*excessive*" cases. This acceptance helped business. It stimulated subscriptions. More people bought "insurance" (or so it was called). More money flowed in and it seemed a shame to stop it. But when disbursements exceeded receipts, that was the time to seek scapegoats. Blame it on the doctors! That was the easiest way! The public of Niagara Falls had been deceived, and by permitting misunderstandings of the contract to persist, and by "accepting" cases, Blue Cross was guilty of the deception.

The implication that excessive utilization was the doctors' fault should not go unchallenged. Doctors were powerless and they were unfairly treated. When the time came to do something about the alleged excessive utilization of hospital service contracts, instead of blaming the doctors, and hurting them, the hospital service corporation should have insisted that the hospitals furnish the service regardless of their rates; and that a campaign be started to correct widespread misunderstanding of the contract and to educate the public on what they were actually buying. This would have entailed no more than a temporary lowering of local hospital rates for Blue Cross cases. Since workmen's compensation cases were being charged less than actual daily costs, this would have been nothing new.

Doctors were not consulted about risks. There were no medical examinations of applicants. Physicians were supposed to "cooperate"—and to explain contracts *after* the patients had purchased them, not before!

In spite of the complete cooperation of the local medical profession from the time the Blue Cross started until the present time, Mr. Metzger seems arrogant and critical. In his Annual Report of the Hospital Service Corporation of Western New York for the year ended December 31, 1943, under the heading: "General Commentary," he says, "In my opinion the medical profession, through its official organization of medical societies and in the Medical Plan, have grossly failed in a realistic attitude toward the needs and demands of the subscribing public." Further on he states, "In last year's report I urged consideration of more comprehensive contracts following a national uniform pattern. A great deal of work has been done on that subject, but the opposition of the medical profession has, in this area at least, checked our efforts short of accomplishment."

Mr. Metzger is condemned by his own statements! What better proof can be offered that the inclusion of medical benefits in group hospitalization contracts will interfere with medical practice and put too much power in lay hands?

Moreover, there is much thoughtful and competent opinion that these problems will not be solved, as Mr. Metzger says, by a "comprehensive coverage contract following a national pattern," whether drawn by Washington "planners," or by private enterprise. Conditions in different localities vary too widely. The reason people don't buy health coverage in addition to group hospital insurance is that they feel they have too many payroll deductions as it is.

It is unfair to blame this on doctors. Today, the hospitals are filled. There is a shortage of manpower. People have full pay envelopes. But what of tomorrow? What of the day that 4,000,000 men and women are released from war production? Where then are payroll deductions coming from? Would it not be more logical for hospital service corporation directors to begin wondering what is going to take the place of these payroll deductions after the war?

In all probability, many of the hospitals and hospital service corporations will have to seek state or federal government subsidies. The question is whether such grants-in-aid to needy hospitals and hospital service corporations will include intolerable lay dictatorship to the medical profession. The doctors left behind should see that the 50,000 physicians in the armed services do not return to political and lay domination of medical and hospital service in the United States.

Case Report

AN UNUSUAL SOURCE OF ERROR IN BASAL METABOLISM DETERMINATION

LEON J. WARSHAW, M.D., New York City

THE determination of the basal metabolic rate by the usual clinical methods is not a difficult procedure and satisfactory tracings may be obtained by the average trained technician. However, the results must be carefully examined in the light of the clinical findings before they are accepted as a true measure of a patient's metabolic activity.

This technic will often lead to the discovery of an error which, if undetected, would have led the physician astray in his diagnosis and treatment. Most of these errors are due to leakage of oxygen from the closed system of the apparatus. In calculating the results, therefore, it will appear that the patient has utilized a larger volume of oxygen per unit of time and will result in the calculation of a higher metabolic rate than actually exists. The most common source of leakage of oxygen, assuming that the apparatus is in good working order, is a poorly adjusted mouthpiece or face-mask. This error can almost always be eliminated by a careful technician with the cooperation of the patient. The following case illustrates a hitherto unreported source of loss of oxygen which can be discovered only by a careful examination of the patient, and which, if undetected, may account for the failure of certain cases of supposed hyperthyroidism to respond to treatment.

Report of Case

A 40-year-old Filipino laborer was admitted to Bellevue Hospital on March 2, 1943, complaining of generalized weakness and weight loss. He had considered himself to be perfectly well until about ten months before admission, when he noted the gradual onset of slight malaise, weakness, and the loss of 30 pounds. These conditions progressed very slowly until about three weeks before admission when he developed mild generalized muscular and joint aches unaccompanied by any objective signs of inflammation. The patient denied any history of chills, fever, night sweats, hemoptysis, anorexia, nervousness, tremors, or skin rashes as well as symptoms relating to the gastrointestinal and genitourinary tracts. He denied known exposure to tuberculosis. The past history and family history were noncontributory.

Physical examination revealed a slight but well-developed, moderately well-nourished male who appeared younger than his stated age. His temperature was 99 F., pulse rate 96, respiratory rate 20, blood pressure 132/84, and weight 104 pounds. The skin was clear and normally moist. The eyes revealed [illegible] There wa[illegible] remarkab[illegible] tympanic [illegible] rounded [illegible] inferior [illegible] injected. There was a full set of teeth in good repair and the tongue was moist and protruded in the midline. The gag reflex was absent. The tonsils were hypertrophied, cryptic, and moderately injected. The pharyngeal mucosa was moderately injected. The neck was supple and the thyroid gland appeared to be normal in size and consistency. [illegible] were of good quality, the first sound at the apex being split and the pulmonic second sound being slightly louder than the aortic. The rhythm was regular and a localized soft, blowing systolic murmur was heard at the apex. The abdomen was soft, no abnormalities being noted other than slight deep tenderness along the path of the descending colon. The genitalia were normal. Rectal examination revealed good sphincter tone and a prostate gland that was normal in size and consistency. The extremities were not remarkable, no tremor or focal weakness being noted. The reflexes were equally [illegible] smear. The urine was normal and examinations of the stool for occult blood, ova, and parasites were negative. The blood Wassermann was negative and the erythrocyte sedimentation rate (Westergren) was 6 mm. in one hour. The serum cholesterol was 100 mg. per cent. A chest x-ray was reported as showing "no infiltration or consolidation of either lung" and x-ray studies of the stomach, duodenum, and colon revealed no pathology.

After a number of days in the hospital, the patient's chart revealed a slightly elevated pulse rate which, even under basal conditions, ranged between 90 and 100. Because of this finding, the history of weight loss, and the low serum cholesterol, a basal metabolism test was ordered and the astonishing figures of +198 and +201 were obtained. In view of the fact that these results were clearly incompatible with the clinical status of the patient, it was assumed that the machine was defective. Accordingly, the apparatus (a Benedict-Roth machine) was dismantled, the parts carefully examined, certain of [illegible] reassembled. Tw[illegible] peated, the results [illegible]

These determinations were carefully reviewed. The patient was reasonably intelligent and cooperative and was under observation throughout the entire determination. He had a complete set of teeth and the mouthpiece fitted well. The tracings were smooth and uniform and the usual [illegible]

From the First Medical Division, Bellevue Hospital, New York City.

was negative. While these results were manifestly unbelievable, nevertheless it was felt that the patient probably did have a mild hyperthyroidism and that a therapeutic trial of iodine was warranted. Accordingly, he was given 10 mg. of Lugol's solution three times daily. There was a very slight clinical improvement but the patient did not gain weight. One week later, the basal metabolic rate was determined to be +48 and +50. Prior to this test, it was suggested that the perforated tympanic membrane noted on admission could have been the source of the oxygen leak responsible for the bizarre results. Therefore, without detaching the apparatus and disturbing the patient as little as possible, the right external auditory canal was packed with cotton soaked in mineral oil. Under these conditions, the results were calculated to be +10 and +21.

Twelve days later, the tests were repeated, four tracings being made. The first, under the usual conditions, resulted in a +210 reading; the second, with the right ear packed, was calculated at +68. The packing was removed for the third and the figure of +208 was obtained. Reinsertion of the packing for the fourth tracing caused a reduction of the rate to +70.

The patient had noted only minimal improvement while on iodine therapy and had gained no weight during his stay in the hospital. At his own request, the patient was referred to the Out-Patients' Department but he failed to keep his appointments.

Discussion

In this case, it was clear that the basal metabolism determinations as performed were of no value in estimating the metabolic activity of the patient. The oxygen consumption varied with the amount of leakage via the eustachian tube and middle ear through the perforation in the tympanic membrane. Since this was a variable factor and since the external auditory canal could not be satisfactorily sealed, no reliability could be placed on the results. Therefore, it is suggested that, in cases where the basal metabolic rate seems high in proportion to the history and clinical findings, and where other sources of oxygen leak have been eliminated by careful technic, the patient's ears be examined to see if a perforation of the tympanic membrane exists.

Summary

A case is presented illustrating the fact that a perforated tympanic membrane may represent a source of oxygen leak during the determination of basal metabolic rate, thereby causing a variable error which leads to the assumption of a higher rate than actually exists.

THE OUTLOOK FOR MENINGOCOCCAL MENINGITIS

Epidemics of meningococcal meningitis are known to occur irregularly in cycles, which usually last from two to five years. There are, in addition, secondary rises and falls in incidence, with peaks occurring during the fall and winter of each year within a large epidemic cycle. During the course of an epidemic a comparison of the incidence of the disease at any time of the year with its occurrence during the corresponding period of the preceding year may therefore give some clue whether the epidemic is waxing or waning, and in this way one may predict whether more or fewer cases are to be expected during the following year and even during the succeeding weeks and months.

A recent summary of the incidence of meningitis, which is included among the morbidity reports of notifiable diseases,[1] indicates that there were more cases during the year 1943 than in 1942. A total of 612,068 cases were reported during the former, and 546,023 cases during the latter. The provisional mortality figures for the first nine months of 1943 show more strikingly the increase in the disease that occurred during that period over the corresponding months of the two previous years.[2] The mortality in thirty-eight states during 1943 was 2.0 per 100,000 of population, as compared with 0.6 during 1942 and 0.5 during 1941. There were deviations from these figures in certain parts of the country, but the great majority of states had rates that were quite similar, both qualitatively and quantitatively. Notable exceptions are Pennsylvania and Montana; in the former the mortalities were, respectively, two and a half and three and a half times as great in 1941 and 1942 as in 1943, and in the latter the 1943 figure was 8.0 deaths per 100,000 population, as compared with 0.4 for each of the two previous years.

More recent figures, however, offer encouraging evidence that the epidemic is subsiding or at least is beginning to decline. In the morbidity reports for the week ending March 11, 1944,[3] the weekly incidence of meningococcal meningitis was lower that that for the corresponding week last year, this being the first time that a decline had been noted. Subsequent reports[4] showed that the downward trend continued during four successive weeks, but during the week ending April 22, the incidence was slightly higher than in the previous year. Such slight irregularities are to be expected, owing to variations in the occurrence of the disease in different parts of the country, and do not necessarily interfere with the general trend of the epidemic incidence; in fact, the very next report[5] indicates that the downward swing was continuing.

Although the epidemic appears to be subsiding, there will undoubtedly be appreciable numbers of cases of meningococcal meningitis during the coming fall and winter, with a peak that will be appreciably lower than that of the past year. Physicians must still be on the lookout for cases and must treat them early and adequately with sulfonamide drugs to keep the mortality at a minimum. One should also be on the lookout for cases of meningococcemia without meningitis, since such patients respond promptly to sulfonamide therapy and since early treatment usually forestalls meningitis and other focal complications, such as arthritis and endocarditis.—*Editorial, New England J. M., July 20, 1944*

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. *The members of the committee are Oliver W. H. Mitchell, M.D., Chairman, (428 Greenwood Place, Syracuse); George Baehr, M.D., and Charles D. Post, M.D.*

"Penicillin and Sulfonamide Therapy"

POSTGRADUATE instruction in penicillin and sulfonamide therapy was arranged for a meeting of the Chenango County Medical Society.

The meeting was held at 1:30 P.M., December 12, at the Norwich Club, Norwich.

Dr. Frederick N. Marty, instructor in clinical medicine, Syracuse University College of Medicine, spoke to the group.

He was presented by the Medical Society of the State of New York and the State Health Department.

Genitourinary Infections

INFECTIONS of the genitourinary tract was the subject of postgraduate instruction that was given before the Wayne County Medical Society, at a meeting on December 12 at 6:30 P.M. at the Hotel Wayne, Lyons.

Dr. Thomas F. Laurie, professor of clinical surgery, Syracuse University College of Medicine, spoke to the group on the subject.

He was presented by the New York State Medical Society and the State Health Department.

MEDICAL AID TO DEPENDENTS OF SERVICEMEN WIDENED

Recognizing the welfare of service men and their families as "a primary obligation," the North Atlantic area of the American Red Cross has adopted a plan providing for admission of "a limited number" of servicemen's dependents to voluntary hospitals without involved investigations of their financial status, E. Roland Harriman, manager of the North Atlantic Area, said yesterday.

The plan, developed by Brig. Gen. Ralph K. Robertson, of the Second Service Command, provides that the city pay $3.25 a day for each patient, the private hospital making up the rest. No money is required from the Red Cross.

"The voluntary hospitals have been most generous for years in the admission of large numbers of servicemen's dependents referred to them by Red Cross chapters," Mr. Harriman said. "A similar cordial cooperation has been given by the city hospitals and the Department of Welfare."

The new plan, he said, will create "a slight difference of emphasis which will make the service of voluntary hospitals more readily available." Proof only of dependency and medical indigence will be required for admission, eliminating the investigation usually made for "charity cases."

AWARD OF SEDGWICK MEMORIAL MEDAL TO DR. GOODPASTURE

Ernest W. Goodpasture, M.D., professor of pathology, Vanderbilt School of Medicine, received the Sedgwick Memorial Medal at the opening ceremonies of the Seventy-Third Annual Meeting of the American Public Health Association in New York City, October 3-5. He is the fourteenth winner of the medal, "For distinguished service in public health."

Doctor Goodpasture is best known for his work in originating a method for cultivating micro-organisms of typhus fever—the so-called Rickettsias. With his coworkers in Vanderbilt University, he discovered that these organisms would grow when planted in a certain portion of the developing hen's egg. This method has now achieved world-wide acceptance and is the basis of the preparation of vaccines for European typhus, the endemic typhus of the southern United States, Rocky Mountain spotted fever, and some of the diseases such as Japanese river fever, the tsutsugamushi disease, that are a serious menace to American troops. He has also made contributions in pathology including the development of a stain by which it is possible to identify the very small elementary bodies of smallpox.—*Health News, Oct. 16, 1944*

GORDON AND LEVINE GET AWARD IN PEDIATRICS

"For outstanding achievement in research in nutrition of infants and children," Dr. Harry Gordon, assistant professor of pediatrics, and Dr. S. Z. Levine, professor of pediatrics at the Cornell University Medical College, were joint recipients of the first annual Borden Award, to be adminstered by the American Academy of Pediatrics. Presented at the Academy's Wartime Conference on Child Health in St. Louis, Missouri, the award was made for metabolic studies on the nutritional requirements of premature and full-term infants. These studies contribute a physiologic basis for individualized feeding.

The Borden Awards, which carry with them a commemorative gold medal and $1,000, were established in 1937 to encourage and give recognition to scientific research in the fields related to the food industry.

They are administered by seven scientific associations.

Congress on Medical Education and Licensure and Annual Session of the Federation of State Medical Boards to Be Held in Chicago in February

The forty-first Annual Congress on Medical Education and Licensure will be held on Monday and Tuesday, February 12 and 13, 1945, at the Palmer House, Chicago. The annual session of the Federation will be held during the Congress.

Following the custom of the last two years, the Council on Medical Education and Hospitals of the American Medical Association will arrange the program for the first day, while the Federation will be responsible for the program on the second day.

The tentative program for the first day indicates that it will be devoted in the forenoon to the general question of Pan-American relations in medicine and medical education. The afternoon session will be devoted to the continuation of education of medical officers, in which the Surgeons General of the Army, Navy, and Public Health Service will participate.

On Monday evening the annual Federation dinner will be held at the Palmer House, at which a prominent speaker will deliver the principal address. The president of the Federation, Dr. J. F. Hassig, of Kansas City, Kansas, will also present his annual address during the dinner program.

The discussions of the second day will be concerned mainly with medical licensure and will be of special interest to state medical boards, as follows:

1. Licensure regulations affecting medical officers returning to civil practice: To what extent will credit be given for military service?
2. Will graduates of nonapproved medical schools be given certain licensure privileges because of military service?
3. The attitude of state boards toward the proposed legislation recommended by the Procurement and Assignment Service of the War Manpower Commission, Washington, D.C., for the temporary licensing of physicians including those who served as commissioned medical officers of the Army, Navy, or United States Public Health Service, as well as those who rendered medical service during the period 1940–1945 in industry or in a civilian community.
4. Relation of licensing boards to the graduates of medical schools continuing the acceclerated program in the postwar period.
5. Advisability of the adoption of the hospital internship as a prerequisite for licensure in the twenty-five states at present not requiring same.

Further suggestions regarding the nature and content of the program will be appreciated.

The Executive Committee of the Federation will meet on Sunday afternoon, February 11, 1945, at the Palmer House, Chicago, the hour and place to be announced later. Business sessions of the Federation will be held following the dinner Monday, February 12, at the luncheon, and following the afternoon meeting on Tuesday, February 13.

All state boards are urged to select their representative to attend the Annual Congress as early as possible and advise the Secretary's office of same.

Hotel and transportation reservations should be made without delay.

National Physician's Committee Met in New York, November 27

DELEGATES attending a meeting of the National Physicians Committee for the Extension of Medical Care at the Waldorf-Astoria on November 27 were warned of the growing strength of forces favoring a broad Federal program of medical care and were urged to "beat them to the punch."

Most of the speakers referred specifically to what they termed the threat of the Wagner-Murray-Dingell bills.

Dr. Morris Fishbein, editor of the *Journal of the American Medical Association*, predicted that similar proposals soon would be made as election campaign issues.

He said there was a considerable number of high-ranking Federal officials who wanted medical care to be "wholly in the hands of lay governmental directors."

Like the other speakers at the all-day meeting, he recommended that private practitioners quickly join together and, in cooperation with representatives of business and industry, offer group medical care plans to take care of the vast majority of all employed persons below the higher income levels.

As an example of what could be done, he referred to a plan developed in Winnebago County, Illinois, in which an insurance company undertook to provide medical coverage for the county's whole population, assembled in groups of five, for $3.00 monthly a family.

Of the 232 attending the meeting, about 25 per cent were members of the National Physicians Committee, an independent organization supported by doctors, medical organizations, and pharmaceutica manufacturers. The conference was the fifth in a series being conducted in various sections of the country.

According to one speaker, the day of individualism in the medical profession had passed. Dr. Herbert D. Simpson, formerly of the Institute of Economic Research, Northwestern University, said, "In the provision of medical care generally in this country, the choice is between two types of institutionalism—private and public."

Statistics to support the committee's program were presented by Dr. Claude Robinson, president of the Opinion Research Corporation, of Princeton, New Jersey, who reported on a national study of group-insurance programs now in effect and an employer-employee opinion survey.

Surveys conducted by the Opinion Research Corporation, he said, indicated that only 5 per cent of the people are concerned about the cost of ordinary illness but that 63 per cent believed there should be something easier than the conventional system of meeting the cost of unusual or catastrophic surgery or illness.

Throughout the nation, according to Opinion Research, 22 per cent of all employed persons work for firms which cooperate with employees in providing some plan for paying the costs of serious illness, and 3,760,468 employees are covered by some sort of group-insurance plan.

IS SODA-BICARBONATE NECESSARY IN SALICYLATE THERAPY

Tablets 5 grains bottles of 50 250 1000
Powder 1 oz. bottles

To be effective, the treatment of acute rheumatic fever must maintain a high salicylate level in the blood [1] When massive doses of sodium salicylate are given by mouth, an undesirable side effect—gastric distress—is frequently encountered To relieve this effect, equal amounts of sodium bicarbonate are given Unfortunately, a decided depression of the blood salicylate level results [2]

Gastric distress and its required relief by sodium bicarbonate are avoided when Salysal is given, for Salysal is not soluble in the acid medium of the stomach Furthermore, 100 parts of Salysal provide 124 equiva lent parts of sodium salicylate [3] Thus, smaller doses accomplish the same effect

Literature and sample on request

SALYSAL

FOR A TRULY POWERFUL SALICYLATE THERAPY

RARE CHEMICALS, INC, HARRISON, NEW JERSEY

[Continued from page 88]

One of the questions asked by Opinion Research interviewers was, "If you had to choose between these two kinds of medical and hospital insurance, which would you prefer: (1) a Federal government plan or (2) a plan sponsored by a group of doctors?"

The report was that 37 per cent answered in favor of the "Federal government plan," 43 per cent said they preferred the "doctors' plan," and 20 per cent said they had no choice.

Medical Chiefs of Armies Hold a Congress; Life-Saving by Penicillin Cited in Brussels

AT ST. Pierre Hospital in Brussels, on December 10, British, American, and Canadian consultants and surgeons pooled their knowledge and experience for saving soldiers' lives.

Maj. Gen. E. Philips, Field Marshal Sir Bernard Montgomery's Director of Medical Services, opened a two-day Medical Parliament of Allied battlefield doctors.

Most of the medical men attending—consultant orthopaedic surgeons, neurosurgeons, ophthalmic surgeons, radiologists, venereologists, anesthetists, and experts in plastic surgery, dermatology, psychiatry, transfusion, and shock—were colonels and brigadier and major generals.

Discussion on "Uses of Penicillin" was introduced by Lt. Col. G. A. G. Mitchel, adviser in penicillin and chemotherapy to the Twenty-first Army Group. He said the old adage that prevention was better than cure was the basis of the penicillin policy of the Twenty-First Army Group.

"Owing to American generosity, it has been possible to extend the use and administration of penicillin," Lt. Col. Mitchell stated. "Arrangements were made that penicillin should be given to cases requiring it at most forward surgical levels, and having once been started it should be carried out, no matter where or how the patient went, until such time as he was able to be evacuated or until some surgeon decided it could be terminated."

Lt. Col. Mitchell said that from D-day to October 31, 2,712 "genuine abdominal wound cases" had been treated with penicillin by British and Canadian forward surgeons. Seven hundred and fifty-nine patients died, giving the recovery rate as 72 per cent, or three out of every four soldiers.

While a number of patients might subsequently die, he said the figures for recovery were still "remarkable."

"Penicillin is now part of the routine of before and after operative treatment of abdominal wounds," said Col. Elliott C. Cutler, chief consulting surgeon for the European Theatre of Operations, United States Army.

New Quarantine Branch Established in Epidemiology Division

A QUARANTINE Branch in the Epidemiology Division, Preventive Medicine Service, has been established under the direction of Lt. Col. Phillip T. Knies, Army Quarantine Liaison Officer. Close cooperation will be maintained with the Public Health Service, the Navy, and other Government agencies concerned with quarantine.

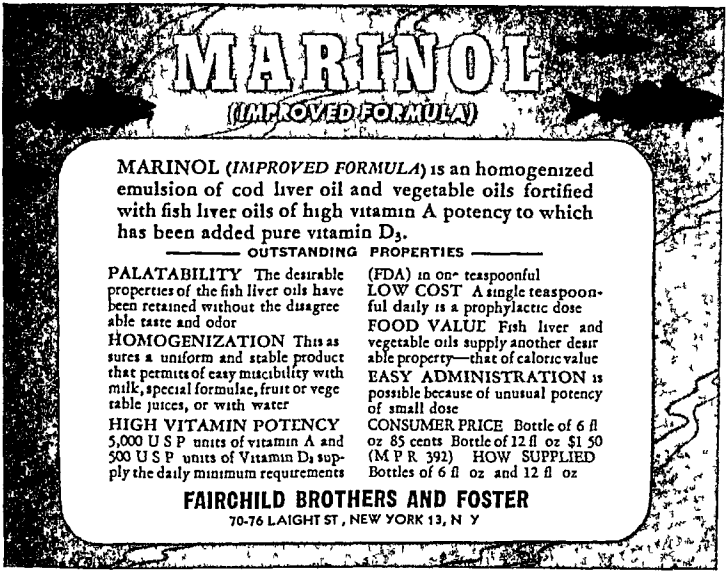
The new program, which aims to extend precautionary measures throughout the Army's far-flung routes of travel, is part of the Medical Department's continuing battle against disease, which has given this country the healthiest fighting forces in the world and the healthiest soldiers in any war in history.

Whereas quarantine in the past has depended mainly upon examination of passengers and cargo on arrival, the new Army quarantine policy takes advantage of the Army immunization program, the constant medical supervision of the soldier, and new methods for the control of insects and rodents.

In addition, the Army will continue to cooperate with civil agencies in the enforcement of existing restrictions against the importation of many plants, animals, and curios which might harbor diseases or pests.

Future developments in the field of quarantine, according to the report submitted by the Interdepartmental Quarantine Commission (which included representatives of the Army, Navy, and Public Health Service), will feature greatly improved methods for the international notification of disease, along with improved health certification of travelers. The extensive military program now being developed is expected to go far in demonstrating the value of new methods growing out of wartime medical progress.

Pediatric Foundation Will Widen Scope



CHARTERED in March, 1944, under the laws of the State of New York, the Pediatric Foundation has issued its first *Bulletin*, which includes a statement of the first two objectives of its flexible program. Those affiliated with the Pediatric Foundation report that, in the future, it will explore other possibilities in which both pediatricians and general-practitioners are interested. At present, the Foundation will center its energies upon these two projects:

To aid in the provision of additional facilities, such as clinics, schools, and camps for the care, treatment, and education of child victims of cerebral palsy, an affliction second only to infantile paralysis as a cause of crippling conditions among children, and

To aid in the provision of additional centers and other facilities for the care, treatment, and special education of child victims of rheumatic fever; and to maintain a demonstration center for the convalescent care of such child sufferers which has been in operation for the past four summers at East Hampton, Long Island.

The new organization is concerned exclusively with fields of service in which needed facilities have not yet been adequately provided. In the future, the Foundation will be interested in launching new projects and in encouraging greater use by physicians and patients of existing activities and facilities of proven worth. It will not duplicate or compete with existing agencies. Nor will it institute or engage in research, which it believes "may be safely left to those individuals and groups who already are pointing out new paths to progress. Excellent research has been done and is being done by highly qualified experts, but too often their conclusions, for want of sufficient facilities, benefit only a few

MARINOL (*IMPROVED FORMULA*) is an homogenized emulsion of cod liver oil and vegetable oils fortified with fish liver oils of high vitamin A potency to which has been added pure vitamin D_3.

OUTSTANDING PROPERTIES

PALATABILITY The desirable properties of the fish liver oils have been retained without the disagreeable taste and odor

HOMOGENIZATION This assures a uniform and stable product that permits of easy miscibility with milk, special formulae, fruit or vegetable juices, or with water

HIGH VITAMIN POTENCY 5,000 U S P units of vitamin A and 500 U S P units of Vitamin D_3 supply the daily minimum requirements (FDA) in one teaspoonful

LOW COST A single teaspoonful daily is a prophylactic dose

FOOD VALUE Fish liver and vegetable oils supply another desirable property—that of caloric value

EASY ADMINISTRATION is possible because of unusual potency of small dose

CONSUMER PRICE Bottle of 6 fl oz 85 cents Bottle of 12 fl oz $1 50 (M P R 392) HOW SUPPLIED Bottles of 6 fl oz and 12 fl oz

needs, while preparing for the responsibilities of the postwar period," he continued.

The following Bronx physicians are serving on the Federation committee with Dr. Goodfriend: Eugene Bernstein, Harris Blinder, Murray L. Brandt, A. Brookner, Louis Carp, Jacob Clahr, Morris Cohen, Mark Daniel, Charles L. Engelsher, Reuben Gilbert, Joseph Golomb, Harry Gordon, David Greenberg, David Ide, Charles C. Kastenbaum, Moses H. Krakow, David M. Kurschner, Philip Liebing, Barney Lifshey, Isidor Palais, Harry D. Pasachoff, Herman Paul Posner, S. S. Rosenfeld, Henry Rother, Samuel B. Schecter, Benjamin Sherwin, Max J. Shulman, Irving Smiley, Abraham B. Tamis, Joseph A. V. Tischler, and Samuel Weiskopf.*

Clinton County

The county society held its annual meeting on November 21 at the American Legion Home in Plattsburg. A business meeting at 5:30 P.M. was followed by a dinner at 6:30 P.M. At the business meeting reports of committees were presented and election of officers was held. After dinner Dr. Harold N. Segall, member of the faculty of McGill University, Montreal, Canada, spoke on "Cardiac Disease."

The new officers are: president, Dr. William H. Ladue; vice-president, Dr. Edwin W. Sartwell; secretary-treasurer, Dr. T. Avery Rogers; censors: Dr. Lyman G. Barton, Jr., Dr. S. Mitchell, Dr. Eric D. Pearson; delegate to state Society, Dr. Leo F. Schiff; alternate delegate, Dr. Phillip B. Barton.

Erie County

A stated meeting of the county society and the Buffalo Academy of Medicine was held on November 24 at 9:00 P.M. in the Georgian Room of the Hotel Statler in Buffalo. The guest speaker was Dr. J. G. Fred Hiss, professor of clinical medicine at Syracuse University College of Medicine, whose subject was "Common Errors in Diagnosis of Heart Disease with Special Reference to Rheumatic Heart Disease."

* * *

Mr. Harold P. Yarvis is the county society's new Executive Officer.

Franklin County

The annual meeting of the county society was held November 15, at 3:00 P.M. in the nurses' classroom at the Alice Hyde Hospital, Malone.

Dr. Paul C. Clark, Syracuse, assistant professor of clinical medicine at the Syracuse University College of Medicine, was the guest speaker. His topic was "Penicillin Therapy."

The business meeting followed Dr. Clark's address. Dinner was served at the Elks Club at 6:30 P.M.

The following officers were elected at the annual meeting: president, John N. Hayes; vice-president, Leon Passino; secretary-treasurer, Daisy C. H. Van Dyke.*

Genesee County

At the annual meeting held last December, at the Court House in Batavia, the following officers were elected: president, Paul P. Welsh, Leroy; vice-president, Sidney L. McLouth, Corfu; secretary-treasurer, Peter J. Di Natale, Batavia; delegate, Peter J. Di Natale.

Greater New York

The family of the service man with facial injuries has a responsibility equal to that of the plastic surgeon in the job of reconstruction, Lt. Col. James Barrett Brown, chief of the plastic surgery section, Valley Forge General Hospital, Phoenixville, Pennsylvania, asserted at the annual Greater New York Dental Meeting at the Hotel Pennsylvania on December 7.

Along with plastic reconstruction of the facial injuries must go the mental readjustment of the patient to his changed appearance, and this readjustment, as important as the work of the plastic surgeon, depends largely on the attitude of the family toward the reconstructed service man, Colonel Brown pointed out. If his family, by its behavior toward him, makes him feel that he somehow is not the same man he was when he left, they unwittingly may do him psychic injury that may prevent him from fully readjusting himself as a useful member of society, he declared.

Warning against exaggerating the possibilities of plastic surgery, Colonel Brown said that, while "we are giving the injured the best modern surgery can provide, we cannot duplicate what God has made."*

Monroe County

Dr. Paul A. Lembcke, Rochester, District Number 4 Health Officer, under leave of absence granted by the New York State Department of Health, has been appointed director of study for the New York State Temporary Commission of Medical Care, according to the Rochester *Democrat and Chronicle*. Dr. Lembcke served as state epidemiologist in 1939. Offices of the commission have been opened in the Terminal Building, Rochester.

Nassau County

The following item is quoted from the Hempstead *Review-Star* of November 10:

> Dr. Austin B. Johnson, president of the county medical society, gave high praise to the Nassau County Cancer Committee in a written endorsement made public today.
>
> At a meeting of the executive committee of the medical society, held early this week, it was voted to endorse the program of the cancer group in Nassau County.
>
> The endorsement, signed by Dr. Johnson, stated: "The medical profession of the county, as well as all Nassau residents, owe a debt of gratitude to this pioneer group, which first organized the tumor clinic at Meadowbrook Hospital in 1933, financed it through its early struggles, gave it the first radium, and then utilized the clinic to create the finest opportunity for postgraduate medical study afforded in Nassau County."
>
> The Nassau Cancer Committee is now at the halfway mark in its annual drive to raise $25,000 to carry on the war against cancer in this county. . . .*

New York County

At the one hundred and thirty-ninth annual meeting of the county society held on November 27 the following officers were elected for 1945: president-elect, Roy B. Henline; first vice-president, Wm. Crawford White; second vice-president, Harold B. Davidson; secretary, B. Wallace Hamilton; assistant secretary, Beverly C. Smith; treasurer, Fenwick Beekman; assistant treasurer, John Carroll; censors, Wm. Bayard Long; W. Laurence Whittenmore; chairman, committee on legislation, Horace E. Ayers; chairman, committee on medical economics, Samuel Z. Freedman; chairman, committee on public relations, John DeP. Currence;

[Continued on page 96]

THE majority of the great revolutions of history have aided the growth of light and knowledge and resulted in benefits for humanity throughout the world. Of such are the qualities attributed to 'SULFASUXIDINE' *succinylsulfathiazole*—the therapeutic use of which "has revolutionized surgical procedures performed on the colon."[1]

Widely accepted as a drug of choice for bacteriostasis in intestinal surgery, 'SULFASUXIDINE' *succinylsulfathiazole*, because of its high concentration in the intestinal tract, is an exceptionally effective enteric bacteriostatic agent. Blood concentration of the drug is low, because it is poorly absorbed from the bowel, and toxic reactions are negligible.

One study of 50 patients who received 'SULFASUXIDINE' *succinylsulfathiazole* before and after surgery of the intestinal tract indicated that "the postoperative course is unusually smooth, that serious complications due to infection following fecal contamination are largely eliminated, and that the period of hospitalization and convalescence is definitely shortened."[2]

The administration of 'SULFASUXIDINE' *succinylsulfathiazole* is particularly efficient in the treatment of acute or chronic bacillary dysentery[3] as well as its carriers.[4]

The compound also has proved effective in the treatment of other lesions and acute infections of the colon such as ulcerative colitis.[5]

'SULFASUXIDINE' *succinylsulfathiazole* is supplied in 0.5 Gm. tablets in bottles of 100, 500, and 1,000, as well as in powder form (for oral administration) in ¼-pound and 1-pound bottles. **Sharp & Dohme, Philadelphia 1, Pa.**

chairman, committee on membership, Carl Binger; trustee for five years, Conrad Berens; delegates to the Medical Society of the State of New York to serve for two years: B. Wallace Hamilton, Alfred M. Hellman, Peter Murray; delegate to serve one year: Clarence G. Bandler.

Dr. Kirby Dwight is president for the current year.

• • •

A meeting open to all physicians and medical students was held by the county society on December 18 at 8:15 P.M.

The scientific session featured four addresses: "Reconditioning from the Standpoint of the Disabled Soldier," by Col. Augustus Thorndike, Office of the Surgeon General, Washington, D.C.; "Problems of Rehabilitation as Seen by the Air Service," by Maj. Donald A. Covalt, MC, Executive Officer, Convalescent Training Division, Office of the Air Surgeon General, Headquarters Army Air Forces, Washington, D.C.; "Retraining the Physically Handicapped," by George G. Deaver, M.D., Institute for the Crippled and Disabled, New York City; "Evaluation of Penicillin from Experience In Military Medicine and Surgery, and Its Application to Civilian Practice," by Maj. Karl F. Mech, MC, Army Service Forces, Chief of Penicillin Section, Halloran General Hospital.

• • •

A Board Meeting of the American Medical Women's Association was held in New York City on December 2. The meeting was attended by chairmen and vice-chairmen of various committees from all over the country. Dr. Alice Stone Woolley, of Poughkeepsie, New York, is president of this organization.

The Board was entertained at a banquet given by the Medical Women's Association of New York City at the Hotel Pierre, December 2, at 7:00 P.M. Dr. Vera Dean of the Foreign Policy Association gave the address of the evening.

• • •

The Bureau of Medical Education has announced the establishment of an office in Room 60 of the Academy of Medicine, 2 East 103rd Street, for the reception and guidance of physicians seeking postgraduate medical courses, and particularly to assist veterans of the present war who are seeking medical instruction upon demobilization.

• • •

Bernard S. Coleman, secretary of the tuberculosis committee of the New York Tuberculosis and Health Association and of the Tuberculosis Sanitorium Conference of Metropolitan New York, has been named new director of the Council of the National Tuberculosis Institutions with headquarters at Denver. He will take over his new duties January 1.

• • •

An intensive course in "X-Ray of the Heart and Great Vessels" will be given at the Mount Sinai Hospital, in affiliation with Columbia University. The course will begin January 5, 1945, and will be held on Fridays. Application should be made to the Secretary for Medical Instruction at the Hospital, Fifth Avenue and 100th Street, New York City 29.

• • •

As a further expansion of the movement in the East Harlem Health District to discover unknown cases of tuberculosis and place them under adequate medical care, a mass chest x-ray survey was conducted in December for the tenants of East River Houses, 105th Street and East River Drive. According to Dr. Eugene O. Chimene, health officer of the East Harlem Health Center, every resident of East River Houses over 15 years of age will be given an opportunity to have a chest x-ray on Friday, December 8, from 3 to 6 P.M. and from 7 to 9 P.M. The survey will be conducted with the aid of a mobile x-ray unit set up in the Child Health Station at 412 East 105th Street. Approximately four thousand persons live in the East River Houses, and on the basis of past experience in work of this kind, it is expected that a substantial number will respond.

"In every large community," said Dr. Chimene, "there are usually a few people who have early tuberculosis without ever suspecting it. If these people continue to go without proper treatment, the disease may develop further and become more difficult to cure. What is more, they may risk infecting others who live or work near them. The purpose of the survey on Friday is to discover any 'unknown' cases of tuberculosis which may exist so that they may secure prompt medical treatment. Tuberculosis can be cured when discovered in time, and the surest way to discover it lies in the x-ray."

Dr. Chimene revealed that for several months the East Harlem Health Center has been offering chest x-rays to apparently healthy adults who could not otherwise afford them at the Health Center building, 158 East 115th Street. From the beginning of the year through November 1, a total of 1,672 chest x-rays averaging 152 a month have been made.

Cooperating with the East Harlem Health Center in its chest x-ray program are the Department of Welfare, the Community Service Society, and the Visiting Nurse Service as well as numerous ministers and teachers in the East Harlem Health District. The Center's tuberculosis education program has included numerous motion-picture programs, lectures, discussion-group meetings conducted by Health Department physicians, and the distribution of a large amount of informative literature designed to acquaint the public with the facts about tuberculosis.

Dr. Bret Ratner addressed the Georgia Pediatric Society at its annual scientific meeting in Atlanta, Georgia, on December 14. His topics were "The Management of the Allergic Child" and "Allergy to the Sulfonamides."

Oneida County

A description of doctors' efforts to obtain penicillin when it was still controlled and limited featured the talk by Dr. Ward J. MacNeal, New York, at the monthly dinner meeting of the Utica Academy of Medicine in the Utica on November 16.

Dr. MacNeal, director of laboratories, New York Post-Graduate Medical School, spoke on "Blood Stream Infections and Endocarditis." As soon as doctors learned of the value of penicillin, they used every possible means, fair or foul, to obtain the drug they believed would save their patients, Dr. MacNeal said.

Lt. Col. Walter S. Pugh, Army Medical Corps, and a member of the Academy, spoke of his experiences in Africa and Italy.*

Onondaga County

A committee on cancer has been created in the Onondaga Health Association with Dr. O. W. H. Mitchell as chairman. This action follows the report of a special committee on inquiry which reported to the Health Association some weeks ago. Copies of the report may be obtained from the Association office in the Loew building.

The duties of the Committee will be to promote popular education concerning malignant diseases and to encourage the proper development and coordination of a community program for cancer control and prevention.

The other members of the committee include Dr. William E. Ayling, Mrs. Lawrence H. Baldwin, Dr. Donald S. Childs, Miss Cathlena A. Cooper, R.N., Commissioner H. Burton Doust, Dr. J. Howard Ferguson, Dr. C. B. Frawley, Miss Franziska Glienke, R.N., Dr. Lee A. Hadley, Mrs. J. J. Levy, Arthur G. Lyons, Robert C. Morris, Dr. Dwight V. Needham, Mrs. Joseph J. Pietrafesa, Mrs. Robert A. Pond, Dr. Carlton F. Potter, Dr. George S. Reed, Mrs. Maynard H. Salmon, Dr. C. A. Sargent, Dr. Nathan P. Sears, Dean Herman G. Weiskotten, Dr. Frederick S. Wetherell, and Mrs. Arthur J. Volles.

The following officers were elected for 1945 at the annual meeting of the county society held on December 5, 1944: president, Dr. Percival K. Menzies; vice-president, Dr. Frederick S. Wetherell; secretary, Dr. Frederick N. Marty; treasurer, Dr. Irving L. Ershler; censors: Dr. DeWitt Brougham, Dr. Lawrence W. Ehegartner; delegate to State Society, Dr. Leo E. Gibson; alternate delegate, Dr. Donald S. Childs; and delegates to the Fifth District Branch: Dr. William R. Dolan, Dr. William O. Kopel, Dr. Joseph H. Walsh, and Dr. George L. Wright.

Putnam County

The regular meeting of the county society was held at the Gypsy Trail Club, Carmel, on Wednesday, December 6, with Dr. Harry M. Rose, instructor in internal medicine, College of Physicians and Surgeons, as the guest speaker. Dr. Rose's topic was "Progress in Clinical Laboratory Methods from the Point of View of the General Practitioner."

Richmond County

The medical magic of penicillin was portrayed by pictures, x-ray films, and actual cases for members of the county society and the Richmond County Dental Society in the Marine Hospital on November 8. Fifty physicians and dentists attended. The dental group was guest of the medical organization at the session.

A description of research work in medical, surgical, urologic, and dental service was given by four staff members at the hospital: Passed Assistant Surgeon H. I. Russek, Surgeon Michele Arthurras, Senior Surgeon Charles Ferguson, and Senior Dental Surgeon Fritz Jackson.

Dr. D. V. Catalano, president of the medical society, expressed the thanks of the Island physicians and dentists to Dr. P. H. B. Anderson, officer in charge of the hospital, and his staff for the demonstration.*

Rockland County

At the annual meeting of the county society held on December 6, at the Wayside Inn, Stony Point, Dr. Edwyn W. O'Dowd, of Tappan, was elected president. The other officers were elected as follows: vice-president, Dr. Frank J. Schwartz, of Spring Valley; treasurer, Dr. Marjorie R. Hopper, of Nyack; secretary, Dr. Robert L. Yeager, Jr., Summit Park; and chairman of the medical economics committee, Dr. Harold S. Heller, of Spring Valley, the retiring president. State Senator Thomas C. Desmond spoke briefly at the meeting. Chester Hammond, of Pan-American Airways, spoke on aviation and showed a motion picture entitled "Across the Pond." Dr. V. DeSalvo played the piano and William Rider sang.

Saratoga County

Officers for 1945 were elected at the 1944 annual meeting of the county society. The officers are as follows: president, Dr. Frederick G. Eaton, Saratoga Springs; vice-president, Dr. Frank A. Mastrianni, Mechanicville; treasurer, Dr. Joseph M. Lebowich, Saratoga Springs; secretary, Dr. Malcolm J. [illegible] Springs.

Schenectady County

The annual meeting of the county society was held at the Hotel Van Curler in Schenectady on December 14. A business meeting took place at 5:30 P.M. at which officers and candidates were elected. Following dinner at 7:00 P.M. Bruce Thomas, war correspondent, spoke and a technicolor motion picture entitled "War Wounds" was shown.

Steuben County

The annual meeting of the county society was held at Bath, on November 9. The following officers were elected to serve the society for the year 1945: president, Dr. Stacy P. Koenemann, Avoca; vice-president, Dr. James Yanick, Hornell; secretary-treasurer, Dr. Rudolph J. Shafer, Corning; delegate, Dr. Leon M. Kysor, Hornell; alternate delegate, Dr. Herbert B. Smith, Corning; censors elected for three years: Dr. Henry E. Elwood, Jr., Corning, and Dr. Ardeen E. Richmond, Wayland.

The society went on record as opposed to the 5 per cent reduction of bills in compensation cases, and they were also opposed to the fee allowed for hernias. It was felt that the assistance fee should be paid in addition to the regular fee of $75.

The scientific program was arranged through the Council Committee on Public Health and Education of the Medical Society of the State of New York and the New York State Department of Health. Dr. William F. Lipp, of Buffalo, spoke on the treatment of jaundice.

Tomkins County

The Central New York Medical Plan, offering treatment to industrial employees and their families in much the same way hospitalization is extended by the Blue Cross, was outlined at the county society meeting in Memorial Hospital, Ithaca, on November 20.

Sponsored by members of the Onondaga County Medical Society and explained by them at the meeting, the medical plan will be extended throughout the Central New York area from headquarters in Syracuse when organization details are completed.

The plan, at first, will be limited to industrial workers with families, it was stated.

Local doctors were asked to join in the movement as underwriting members of the corporation.*

Warren County

According to the *Glens Falls Times*, the following officers were elected for 1945 at the annual meeting of the county society: president, Dr. Burke Diefendorf, Glens Falls; vice-president, Dr. Patrick H. Huntington, Warrensburg; secretary-treasurer, Dr. Lester C. Huested, Glens Falls.

Westchester County

Dr. Laurance D. Redway, Ossining, was elected president of the county society at the one hundred and forty-seventh annual meeting on November 21 at the New York Hospital, Westchester Division, where guest speakers stressed the importance of voluntary medical insurance for all people of the lower income groups.

Guest speakers included Dr. Edward R. Cunniffe, New York City, president-elect of the Medical Society of the State of New York, and Dr. Louis H. Bauer, Hempstead, Speaker of the House of Delegates of the State Society and trustee of the American Medical Association. Local physicians participating in the discussion included Dr. George C. Adie, New Rochelle; Dr. Robert B. Archibald, Bedford Hills; Dr. James F. Parsons, Dobbs Ferry, and Dr. Ralph T. B. Todd, Tarrytown.

All speakers agreed that establishment of a prepayment plan of medical care which would be financially sound, would permit free choice of a physician by the patient, and would provide a high quality of care is the most important task facing the medical profession today.

Dr. Merwin E. Marsland, Mamaroneck, retiring president, made recommendations concerning the business and educational activities of the society and Dr. Redway, incoming president, reviewed the society's history, pointing out that its first meeting in White Plains in 1797 was only twenty-two years after the Battle of Lexington.

Other officers elected were Dr. Isadore Zadek, Mount Vernon, president-elect; Dr. Archibald, vice-president; Dr. Henry E. McGarvey, Bronxville, secretary, Dr. W. Alex Newlands, Tarrytown, treasurer; censor, Dr. Maximin D. Touart, Bronxville; special committee on war participation, Dr. McGarvey; subchairman on public health committee, Dr. Touart; legislative committee chairman, Dr. Waring Willis, Bronxville; membership committee, Dr. Thomas E. Uniker, Bronxville; and public relations, Dr. Henry W. Kaessler, Bronxville.

AMERICAN LIBERTY AND THE WAGNER-MURRAY-DINGELL BILL

No charitably minded citizens can overlook the fact that there are many provisions in the Wagner-Murray-Dingell Bill which incline toward a new order.

But the naiveté and novelty of the bill, the cadginess and the codlingness of it, the "I am my brother's keeper" gospel of it, are so acceptable, not just to the lame and the halt but to the tame and the dolt, that opposition to any portion of it and on any score is doubly difficult. Therefore, such opposition must be doubly impelling, incisive, intelligent, and invincible. As such, it must reach legislators and representatives by way of the people who elect them, a people who will have to be convinced by sound arguments that this "cradle to the grave" program is not compatible with our idea of American liberty.—*Ivor Griffith, President, American Pharmaceutical Ass'n., in Med. World, Sept., 1944*

College of Surgeons Announces 1944 Approved List of Hospitals

THE American College of Surgeons announces that 3,152 hospitals in the United States and Canada are included in the 1944 Approved List. The list is published in the annual Approval Number of the College *Bulletin* issued December 31.

A total of 3,911 hospitals were included in the 1944 survey and the approved hospitals represent 80.6 per cent.

The first annual survey, made in 1918, included 692 hospitals of 100 beds or over, of which only 89, or 12.8 per cent, merited approval. Hospitals of 25 beds and over are covered in the current surveys.

A total of 2,342 hospitals of 100 beds and over were on the 1944 survey list, and 2,182, or 93.1 per cent, were approved. A total of 1,119 hospitals of 50- to 99-bed capacity were under survey of which 789, or 70.3 per cent, were approved. A total of 450 hospitals of 25- to 49-bed capacity were under survey of which 181, or 40.2 per cent, were approved.

On December 31 of each year the ratings of hospitals under survey by the American College of Surgeons automatically terminate. The status of every hospital based upon all data collected from the current survey is reconsidered each year.

"When the Lid's Off"

THE removal of priorities on many kinds of civilian goods as soon as Germany has been defeated may create real problems for hospitals. There won't be enough goods to go around. Under present priority controls, hospitals get first break. Without priority they may be hard put to obtain needed supplies and equipment. While no one wants to continue the priority system one minute longer than necessary for the national safety and welfare, the continued operation of hospitals is so important an element in national welfare that earnest consideration of this problem should be given by the War Production Board.—*The Modern Hospital, Nov., 1944*

Hospital Association Elects Head

DR. PETER D. WARD, St. Paul, was chosen president-elect of the American Hospital Association at its annual meeting in Cleveland in October, and Dr. Donald C. Smelzer, Philadelphia, was inducted into the presidency.

The vice-presidents who were elected at the meeting are Harold A. Grimm, Millard Fillmore Hospital, Buffalo; Rev. George Lewis Smith, Diocese of Charleston, Aiken, South Carolina; and A. J. MacMaster, R.N., Moncton Hospital, Moncton, New Brunswick, Canada. Other officers include Dr. Harley A. Haynes, Ann Arbor, Michigan, treasurer, and Mr. George Bugbee, Chicago, executive secretary.

Improvements

The New York Hospital announced on December 4 that construction had begun on an expansion program which will increase the number of beds at the hospital from 977 to 1,138 by the middle of next summer. Material and equipment priorities were granted by the War Production Board.

The improvements will provide 161 beds in the medical, surgical, and children's departments, as well as enlarged x-ray and other departments and laboratories for research in penicillin, the sulfa drugs, and treatment of combat injuries.

The building program will cost about $600,000, but will not require the construction of any new unit. A formerly unused floor will be developed for use and other sections of the building will be altered and rearranged. The program will be completed without interrupting any of the hospital's services.*

• • •

An iron lung credited with saving at least one life was presented on December 9 to the Jewish Memorial Hospital in New York City by Liberty Post, No. 22, of the American Legion. The gift was accepted on behalf of the institution by its president, Milton M. Goldsmith.*

• • •

X-ray equipment valued at more than $10,000 and used at the Infantry Armory in Utica by the armed forces induction station's mobile team, which recently completed three years of activity, will be sent to Rhoads Hospital.*

At the Helm

Appointment of Dr. Francis D. Shaw as director of Dannemora State Hospital, Dannemora, effective December 1, has been announced by State Correction Commissioner John A. Lyons.

Dr. Shaw, now associate director at Matteawan State Hospital, in Beacon, succeeds Dr. Blakely R. Webster, who is retiring after thirty-two years with the department.*

• • •

Lt. Comdr. Thomas Henry Argue, former Corning physician, who recently returned after thirteen months' service in Puerto Rico, has been appointed chief of surgery for the Naval Hospital at Marine Corps base, Camp Lejeune, North Carolina, according to an official release. He left November 12 for his new assignment.

Lt. Comdr. Argue is serving his third enlistment

with the armed forces. He interrupted his studies at Harvard University from September to November in 1918 to join the Army, and from 1926 to 1936 he held a lieutenancy in the Army Reserve. He received the doctor of medicine degree at Harvard in 1924.*

• • •

Formal announcement of the recent appointment of Dr. William Henry Shehadi as chief of the x-ray department of Mount Vernon Hospital, succeeding the late Dr. Ludwig B. Goldhorn, has been made by Arthur L. Zerbey, president of the board of managers.*

• • •

Dr. Francis B. Trudeau, of Saranac Lake, has been elected president of the board of trustees of Trudeau Sanatorium.

Dr. Trudeau succeeds Dr. James Alexander Miller, of New York City, who has served as president of the Board for the past seventeen years. Dr. Miller will remain a trustee.

Dr. Fred H. Heise of Trudeau Sanatorium was elected chairman of the medical board. He will fill the vacancy left by Dr. Trudeau.

Other officers on the committee named to office were Dr. William P. Thompson, of New York City, secretary, and Frederick Sheffield, of New York City, treasurer.

Additional Saranac Lake physicians who will serve again in their respective offices are Dr. Edward R. Baldwin as chairman of the executive committee and Dr. L. U. Gardner as director of Trudeau Foundation and the Trudeau School.

Dr. Winfield O. Kelley, of Saranac Lake, was elected as consulting surgeon for the Sanatorium.*

• • •

Dr. A. P. Merrill, medical director of St. Luke's Hospital, Chicago, will become superintendent of the Home for Incurables, 2751 Grand Concourse, Bronx, on January 1. This appointment, to succeed the late Dr. Moody S. Arnold, was announced today by Ernest Iselin, president of the institution.

Dr. Merrill is a graduate of Leland Stanford University where he also got his degree in medicine. He served his internship at the San Francisco County Hospital and his surgical residency at Stanford University Hospitals. After a few years of private practice he became assistant superintendent of San Francisco County Hospital from which post he went to St. Luke's in Chicago.

Home for Incurables was founded in 1866 and has been a member of the United Hospital Fund since 1880.

Newsy Notes

The twenty-one buildings of the United States Veterans Hospital in Kingsbridge Road, the Bronx, were inspected on December 13 by a group of veterans' representatives and newspaper reporters, preparatory to the opening of a campaign to raise $10,000,000 by the Disabled American Veterans.

The funds raised in the campaign will be used over a ten-year period to train special service officers and supervise the 504 discharge centers in the United States, and to pay the salaries of the men. Those selected for the training course must be wounded veterans. They will receive six months' instruction in the American University at Washington, then will have six months' field work and a term of administrative work before being qualified. They will be certified by the Veterans Administration to represent the claims of disabled service men before various boards.*

• • •

Assistance and facilities of Vassar Hospital have been placed at the disposal of the Poughkeepsie Common Council for the purpose of providing communicable disease hospital accommodations in Duchess County.

The special committee of the council was designated to work with the Dutchess County Medical society in furtherance of the effort of the society to provide the special hospital facilities.*

• • •

Columbia-Presbyterian Medical Center recently announced that the hospital will institute a pension plan that will not require any contribution from employees. It becomes effective January 1. The plan replaces an optional plan begun in 1931 to which employees contributed if they so desired. The new plan will automatically cover employees who have reached the age of 30 and completed two years of employment at the hospital. It provides for retirement at 65 on an annual pension amounting to one per cent of the total compensation received during the period, with a minimum retirement annuity of $40 a month. A group life insurance plan on a contributory basis will also be offered.

• • •

A gift of $50,000 in Government bonds was recently made to the United Hospital Fund of Greater New York by Flora R. and Isador M. Stettenheim as a memorial to Ivan M. Stettenheim.

• • •

New York area hospitals have made an appeal for old radios, and the United Electrical Radio and Machine Workers of America, CIO, 100 W. 42nd Street, New York City, are collecting and repairing radios for the hospitals. They are delivered to the hospitals in good condition a few days after they are received by the Union. Pupils in the War Industries Training Program are doing much of the actual repair work.

• • •

Nine days before its fifty-seventh anniversary, Memorial Hospital for the Treatment of Cancer and Allied Diseases admitted its 100,000th patient. Public education about cancer is progressing well, George F. Holmes, hospital superintendent for the last thirty years, said in commenting upon the institution's birthday, and cancer now awaits further research and the training of more doctors.

A LITTLE POWDER A LITTLE URINE

Color reaction immediately, if . . . acetone or sugar is present. These two important short cuts simplify routine urinalysis!

Acetone Test (DENCO)
AND
Galatest

The same simple technique used in testing with Galatest (the dry reagent for the immediate detection of urine sugar) is also employed for the acetone test.

Acetone Test (Denco) detects presence or absence of acetone in urine in one minute. Color reaction is identical to that found in violet ring tests. A trace of acetone turns the powder light lavender—larger amounts to dark purple.

A handy kit containing one vial of Acetone Test (Denco) and one vial of Galatest is now available. This is very convenient for the medical bag or for the diabetic patient. The kit also contains a medicine dropper and a Galatest color chart. This kit and refills of Acetone Test (Denco) and Galatest, are obtainable at all prescription pharmacies and surgical supply houses

Accepted for advertising in The Journal of The American Medical Association

out Governor Dewey's recommendation for post-war improvement and expansion of facilities at State mental hygiene institutions which he had described as "overcrowded by 20 per cent."

The Post-War Public Works Planning Commission announced approval of eighty-three projects at twenty-four institutions involving construction work estimated to cost $52,474,643. Plans for the expenditure of $9,163,893 are completed or begun and will be started for the remainder immediately, the commission said.*

Castle Point Veterans' hospital has just celebrated the twentieth anniversary of its dedication. The hospital, formally dedicated in 1924, has since become an outstanding federally maintained tuberculosis center in the East.*

• • •

Increased benefits to the 1,700,000 members of the Associated Hospital Service of New York were announced on December 1 by Louis H. Pink, President.

Beginning on December 1 subscribers will be entitled to receive hospital care during a period of 21 days for each separate illness they may suffer instead of 21 days for the entire year. The organization's policy of granting benefits for 90 extra days at one-half the regular hospital rates will remain in effect for each period of hospitalization. In addition a cash allowance of $7.25 will be paid to subscribers who may need operating room service at the hospital but who do not become bed patients.

"These benefits have been granted," said Mr. Pink, "in keeping with our basic policy of sharing with members and their families all surpluses beyond those necessary for sound operation. They will be continued as long as our financial condition permits us to do so. Whenever our experience with added benefits proves favorable over a reasonable period of time, they are included in the contracts of our subscribers."

AMERICAN REVIEW OF SOVIET MEDICINE BEGINS SECOND YEAR

The full story of how surgeons in the USSR are reconstructing male genital organs injured or destroyed in the war has been revealed here for the first time by the Soviet doctor who did the pioneer work in this surgical field.

The doctor is A. P. Frumkin, professor of surgery at the Urologic Division of the Botkin Hospital in Moscow. Writing in a recent issue of *The American Review of Soviet Medicine*, bimonthly publication of the American-Soviet Medical Society, Frumkin declares that "a complete loss of the external genitalia is a rather frequent occurrence in the present war," and that "this type of injury is extremely serious, since it precipitates the patient into a state of severe depression."

This issue of the magazine marks the beginning of its second year of publication. Associate editors who have just been added to the staff are Dr. Gregory Zilboorg, well-known psychiatrist, and Dr. Jacob Heiman, clinician. Dr. Henry E. Sigerist, editor of the journal and director of the Institute of the History of Medicine at Johns Hopkins University, is currently in India, at the official request of the British and Indian governments, where he is making a study of health conditions. Dr. Sigerist is considered the foremost authority on public health in this country. He is to return next month.

The same issue of *The American Review of Soviet Medicine* also features a short review of the work of the Rehabilitation Clinic established in the Neurologic Division of the All-Union Institute of Experimental Medicine in Moscow. The author, A. R. Luria, a professor at the clinic, writes that "experience with physical therapy in wartime has changed many old concepts still prevalent."

Vladimir P. Filatov, Soviet scientist, describes in the journal how the Russians obtain and prepare tissue from human cadavers, and how they are preparing the way toward the use of eye banks and tissue banks as widespread as blood banks.

COMMITTEE FOR MENTAL HYGIENE PUBLISHES DIRECTORY OF PSYCHIATRIC CLINICS

The National Committee for Mental Hygiene has announced the publication of a new directory of psychiatric clinics and related facilities in the United States, with special reference to rehabilitation needs of veterans.

This directory is broader in scope than any previous ones, according to the Committee. It is primarily for medical officers and other professional staff in the armed forces and the American Red Cross who advise men about to be discharged regarding sources for psychiatric treatment and related services. It is also for the use of professional workers in civilian agencies in advising clients or referring persons to agencies in any part of the country. The directory lists state-wide facilities, such as state hospitals and other institutions for the mentally handicapped, state departments dealing with clinics, state societies for mental hygiene, Veterans Administration neuropsychiatric hospitals, and Veterans Administration regional offices; community psychiatric clinics and other resources, listed by state and city; family welfare societies; councils of social agencies; American Red Cross Home Service agencies, etc.

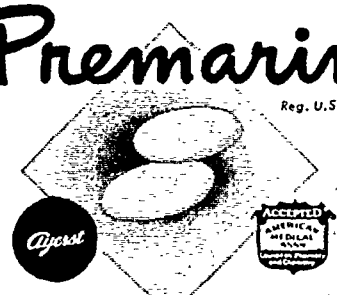
NO. 4 OF A SERIES • • • "PREMARIN" THERAPY AT THE MENOPAUSE



Well Tolerated

The therapeutic effect of an estrogen cannot be measured in terms of potency alone. When the menopausal patient is disturbed by a complexity of unpleasant side effects, therapy is really only partially effective . . . actually, the patient often "exchanges one set of symptoms for another". In "Premarin", however, the physician will find an estrogen of high potency, yet exceptionally well tolerated. "Premarin" is derived exclusively from natural sources; it is remarkably free from unpleasant side effects, and has the desirable property of imparting a feeling of well-being.

Office Hours—*24 hours a day*

• Battle front or home front—the story is the same: There aren't enough hours in the day.

It may be a new offensive in the far-off Pacific with its inevitable toll of casualties; it may be an epidemic in a crowded defense area here on the home front—but *never* in history of man has the medical profession carried such a responsibility . . . carried it so magnificently.

But the reward is great. Victory over the aggressors, yes, certainly. And beyond that, victory over an enemy stronger than Germany or Japan. Because terrible though war is, it is the laboratory out of which will come new knowledge to benefit mankind for years to come.

NO ONE more than the busy doctor deserves that precious moment of relaxation . . . the pleasure of a cigarette. Likely as not it will be a cool, flavorful Camel—the favorite cigarette with men in all the services, according to actual sales records.

...TREATMENT OF PREGNANCY *is Indicated*

In acute cholecystitis, hemolytic or catarrhal jaundice, and cirrhosis or atrophy of the liver, pregnancy is usually contra-advised for the safety of both mother and child. • This holds true also for patients with symptomatic cholelithiasis, presenting severe and frequent attacks, until surgery has effected a definitive cure. For (even under most favorable conditions) childbearing seriously taxes hepato-cystic integrity, frequently disturbing gallbladder motility, cholesterol metabolism and bile salt synthesis • For the safe control of conception, Ortho-Gynol Vaginal Jelly is widely advocated. It is promptly spermicidal . . . non-irritant even on extended application . . . and esthetically appealing.

Physiologic drainage TO RELIEVE GALL BLADDER STASIS

A new and clinically successful plan of treatment of bile tract dysfunction involves these 3 steps based on a truly physiologic approach

KETOCHOL—1 to 2 tablets t i d , to promote an increased production of aqueous, free flowing bile by the liver

PAVATRINE with PHENOBARBITAL—antispasmodic sedative medication—to relax the sphincter of Oddi and reduce biliary-gastrointestinal spasm

DIET—rich in uncooked fats, eggs, milk, cream—for its cholagogue effect

KETOCHOL . . a nontoxic combination of *all four* of the oxidized (keto) form of those bile *acids* normally present in human bile

PAVATRINE with PHENOBARBITAL . . the new, safe, *non narcotic* antispasmodic (*β* diethylaminoethyl fluorene 9 carboxylate hydrochloride), 125 mg (2 gr), with the dependable sedative, phenobarbital 15 mg (¼ gr)

"YOU'LL FIND THE SPA A FRIEND IN TIME OF NEED, AS I HAVE"

. . . says the harassed practitioner whose wartime load it has helped to lighten.

Saratoga Spa is accommodating an unusually large number of patients suffering from such conditions as cardiac, vascular or rheumatic disorders which may be aggravated by wartime strain.

A large proportion of these men and women are patients of practicing physicians who have found the treatments here very beneficial to former patients.

The facilities which New York State has erected around the famed mineral waters of the Spa are extensive. They will provide amply for the needs of your own patients for whom restorative treatment is indicated, under regimens of care which you yourself have recommended.

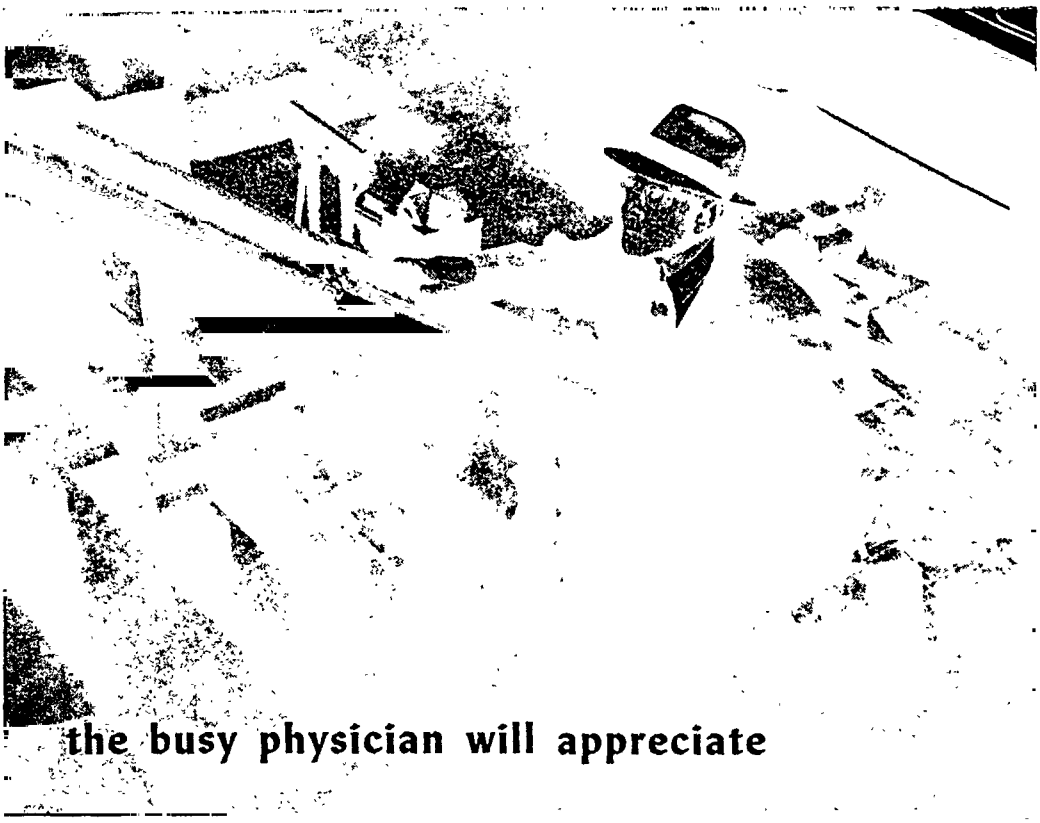
For professional publications of The Spa, and physician's sample carton of the bottled waters, with their analyses, please write W. S. McClellan, M.D., Medical Director, Saratoga Spa, 155 Saratoga Springs, N. Y.

SARATOGA SPA

THE EMPIRE STATE'S CONTRIBUTION TO THE MEDICAL PROFESSION

Gushing water is bound to get coverage—bound to get absorption.

Patients with pernicious anemia are bound to receive effective treatment with Purified Solution of Liver-Breon; when the solution is injected, material derived from but 1/30 as much liver need be given as when administered by mouth. The injection brings about rapid remission of the symptoms; absorption is certain; massive doses are possible more economically; and further, there is a storage effect permitting infrequent injections. Purified Solution of Liver-Breon is available in two strengths, both meeting the standards of the Anti-Anemia Preparations Advisory Board.



Supplied: 5 U.S.P. (Injectable) Units per cc in 10 cc vials;
10 U.S.P. (Injectable) Units per cc in 5 cc and 30 cc vials.

the busy physician will appreciate

these important advantages of

PYRIDIUM.

- Prompt, *gratifying* relief of distressing urinary symptoms
- Ease and convenience of administration
- Safety—lack of toxicity

Increasing numbers of busy physicians are finding Pyridium to be a thoroughly dependable chemotherapeutic agent upon which they may rely for prompt, gratifying relief of the distressing symptoms encountered in cystitis, prostatitis, pyelonephritis, and urethritis.

Clinical experience extending over more than a decade, as reported in the published literature on Pyridium, testifies to its prompt and effective action and its freedom from narcotic or irritant effects.

More than a decade of service in urogenital infections

You would prefer 14" x 17" Radiographs

For diagnostic quality, for readability alone, wouldn't you prefer full-size radiographs in all examinations?

Because of the evident advantages (because physicians and roentgenologists themselves favor it), Powers X-Ray Service has standardized on the full-size 14" x 17" radiograph for group chest examinations. Produced by the Powers Roll Paper Method, now in its 12th year of use, these radiographs feature:

1. ACCURACY. Powers' Radiographs feature the same depth and tone from print to print, enabling the examining physician to make accurate comparisons of serial exposures.

2. HIGH DIAGNOSTIC QUALITY. Over 3 million successful radiographs testify to the quality of the Powers method. Within the limitations of large-scale examinations, Powers' Radiographs are brought to the highest degree of accuracy. *That means fewer missed cases of early lesions!*

3. EASE OF READING. Because they are *full-size*, Powers' Radiographs save time and eyestrain for the interpreting physician. Special viewers are supplied as part of the Powers Service.

4. SPEED AND ECONOMY. Trained Powers technicians set up the portable equipment and operate it—at a rate as high as 150 subjects per hour. The cost is less than any other method offering comparable quality—*considerably* less when the cost of cases missed by less effective methods is considered.

POWERS X-RAY SERVICE is available anywhere in the United States for large-scale examinations. Interested physicians are invited to write for further details to:

POWERS X-RAY SERVICE

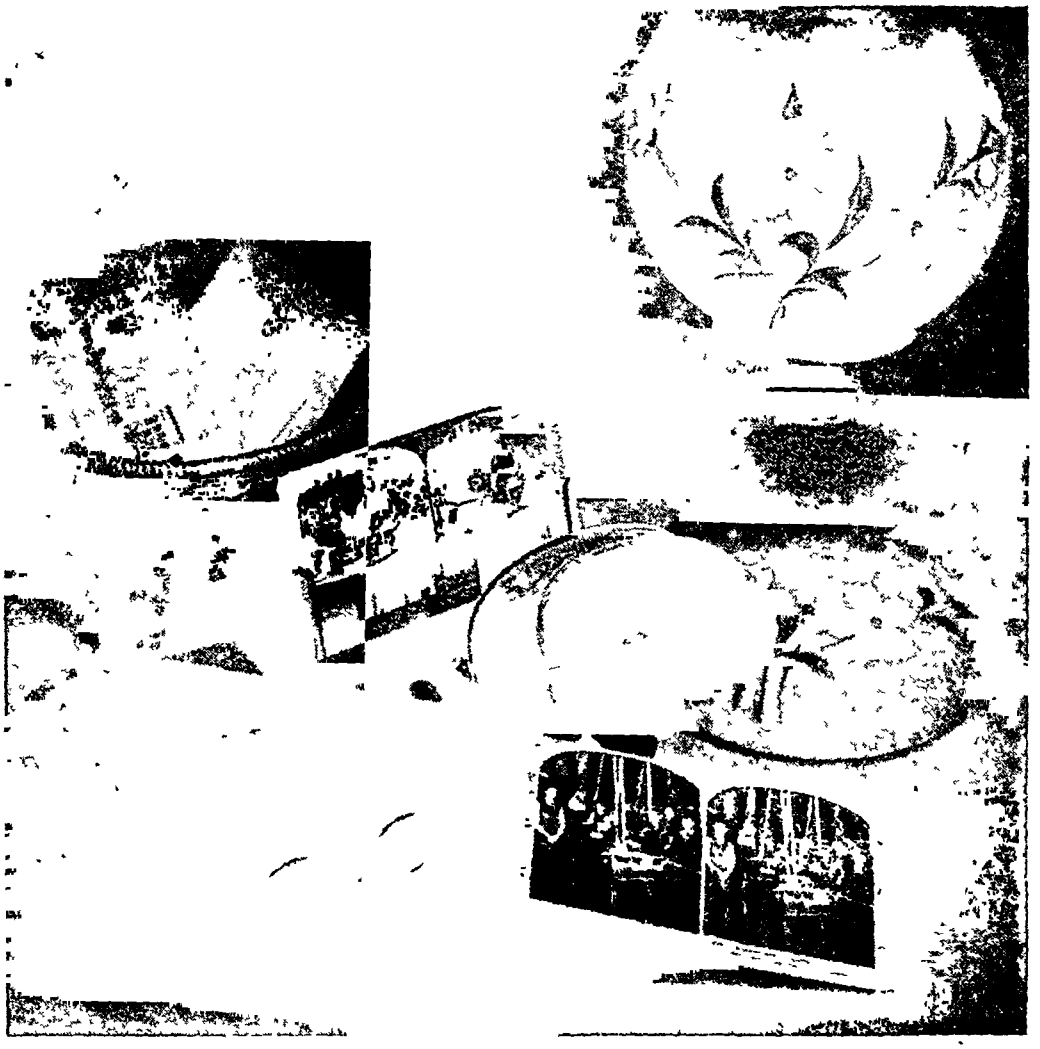
BLOOD ENRICHMENT

IN IRON-DEFICIENCY ANEMIA



The blood in iron-deficiency anemia is markedly benefited by Copperin administration: hemoglobin percentages quickly rise; red blood cells increase in quantity and improve in quality.

Due to the action of the catalyst, copper sulphate, the amount of iron ammonium citrate per capsule is reduced to only 32 Mgm. But as ALL the iron is made available, maximum therapeutic effect is obtained. Copperin does not stain teeth or irritate the gastrointestinal tract and is water soluble. Prescribe Copperin "A" for adults, Copperin "B" for children.

COPPERIN

1895 X-RAY'S SEMICENTENNIAL *1945*

1895 ! Chronicled one of the world's greatest scientific discoveries, which brought immortal fame to modest William Conrad Roentgen, University of Wurzburg physicist. Instinctively a scientist, he investigated a phenomenon of light observed while experimenting with an electrically-charged vacuum tube. Today, mankind, in profound gratitude, commemorates Roentgen's contribution—*the X-ray.*

This year, we at G. E. X-Ray also celebrate the 50th Anniversary of the founding of Victor Electric Company (presager of our present organization) by those two well known pioneers, the late Mr. C. F. Samms, and Mr. J. B. Wantz who, as Consulting Engineer, continues a notable career.

Our past record of service to x-ray science speaks for itself and for our future efforts in the interests of this science.

Relief of Spasm

DONNATAL has been found dramatically effective in gastro-intestinal conditions of spastic origin

By providing predetermined quantities of belladonna alkaloids, Donnatal assures *reliability of action* in producing smooth muscle relaxation *without the danger of toxicity.**

And the addition of phenobarbital, affording *non-narcotic sedation* of the central nervous system, is highly efficacious in controlling the psychogenic factor so frequently encountered — particularly in spastic conditions of the gastro-intestinal tract.

Moreover, this ideal spasmolytic — in convenient tablet form — costs *only about half as much* as synthetic preparations (less even than tincture of belladonna and elixir of phenobarbital)

Donnatal is indicated in a *wide range of spastic disorders,* including pylorospasm, hyperchlorhydria, intestinal irritability, dysmenorrhea, etc

A. H. ROBINS COMPANY, INC.

RICHMOND 19 • VIRGINIA

*DONNATAL IS PRACTICALLY FREE FROM THE UNPLEASANT SIDE REACTIONS OF ATROPINE

FORMULA Each tablet contains the alkaloids of Hyoscyamus, atropine and scopolamine equivalent to approximately 0.3 mg. hyoscine hydrobromide (gen. 1/4 gr.) phenobarbital AVAILABLE in bottles of 100 tablets.

A WOMAN'S PEACE OF MIND

No one understands the complexities of a woman's mind as well as her physician He is fully aware that the menstrual period may often initiate temporary psychosomatic difficulties, or aggravate existing emotional maladjustments

Today – with so many exacting demands upon women – any measure which contributes to her greater sense of comfort and well-being merits the physician's special attention

Perhaps no single measure brings a woman such a welcome sense of physical and mental relief during the menses as the use of TAMPAX, the original vaginal tampon for improved menstrual hygiene

This is because TAMPAX fits so comfortably in situ eliminates all external bulkiness, precludes the possibility of exposure of the discharge to odorous decomposition abolishes vulvar irritation and chafing from perineal pads and permits freer indulgence in sports and other physical activities

Results of recent studies[1 2 3] in thousands of cases confirm the fact that TAMPAX meets all the requirements of modern hygiene – providing thoroughly *adequate* and *safe* protection Equally important (as one gynecologist has stated), with TAMPAX ' many patients say they can forget that they are menstruating and so are without the disturbing annoyance they had every time they menstruated "[1]

Increased Flow and Thinner Bile...

AN ESSENTIAL IN THERAPY

Not only in the conservative management of hepatobiliary disease, but also before and after gallbladder and common duct surgery, free flow of thin liver bile is an integral part of therapy. Impairment of bile flow —whether due to secretory deficiency, faulty bile composition, narrowed lumina of the biliary pathways due to hyperplasia or edema, or biliary dyskinesia—must be promptly overcome.

Decholin (chemically pure dehydrocholic acid), by its specific hydrocholeretic action, produces a copious flow of thin liver bile, under an increased pressure which proves efficacious in flushing the intrahepatic and extrahepatic passages, tending to free them of inspissated bile, gravel, and mucopurulent material. In the hands of many outstanding clinicians Decholin is a sine qua non in hepatobiliary disturbances. It is contraindicated only in complete obstruction of the hepatic or common bile duct. Supplied in boxes of 25, 100, 500 and 1000 3¼ grs. tablets.

"IN UNION THERE IS

Better creosote therapy

• It is not surprising that physicians call CALCREOSE "a happy combination". In this popular cough preparation, the potent bronchial expectorant and antiseptic—creosote—is chemically combined with calcium . . . thereby increasing creosote's bacteriostatic and bactericidal action up to three times, and (at the same time) insuring equally good absorption[1].

• Thus, Calcreose possesses all the well-known benefits of creosote[2], yet successfully masks its disagreeable odor and taste.

• In many bronchial and respiratory affections, Calcreose will aid in lessening cough, diminishing expectoration, reducing its purulency, and deodorizing sputum (in fetor of bronchial secretions).

• Especially important: Calcreose is freely tolerated; even in large doses, it causes no gastric irritation or nauseous reaction!

[1]Fellows, E. J.: J. Pharm. & Exper Ther., 60:178, 183, 1937.

ANNOUNCING

White's

OTOMIDE

an effective new means of local chemotherapy for suppurative and non-suppurative infections of middle and external ear

This noteworthy new preparation fulfills the requirements of possibly the most serviceable type of "ear drops." It is *effectively* antibacterial, analgesic, hypertonic, yet non-irritating.

White's Otomide is a stable solution containing:

	W/V
Sulfanilamide	5%
Urea (Carbamide)	10%
Chlorobutanol	3%
Glycerin (high sp. gr.)	q.s.

The advantages of carbamide-sulfonamide in topical treatment of localized infections are established.[1, 2, 3] Carbamide (urea) alone has been successfully used in acute and chronic middle ear disease.[4, 5, 6] Its association with sulfonamide enhances antibacterial activity, inhibits sulfonamide-antagonists present in purulent exudates. Chlorobutanol is included for its analgesic and antipruritic properties.

• *NOTE:* Sulfanilamide has been selected as the sulfonamide of choice because of its greater solubility in tissue fluids, and because "(it) diffuses more rapidly . . . (and) appears to be the least harmful of the commonly used sulfonamides to regenerating tissue."[7]

Indications—local prevention and treatment of the usual bacterial infections of the middle ear and external auditory canal.

White's Otomide is supplied in dropper bottles of one-half fluid ounce (15 cc.)—on prescription only. White Laboratories, Inc., Pharmaceutical Manufacturers, Newark 7, N. J.

Breakfast can be Quick and Nourishing

when whole grain or enriched cereals make the main dish

NO one knows better than the Medical Profession the need for an easily assimilated, good-tasting and nourishing breakfast.

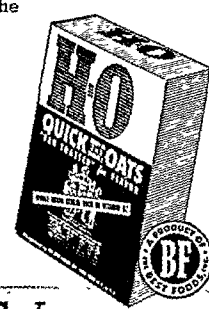
The problem comes in fitting this into sip-and-run habits—and that's where H-O comes to your aid.

Recognized as one of the best sources of grain protein, oats lead all other grains in food-energy as well. They also provide natural Vitamin B_1, calcium, nutritional iron and phosphorus.

To this, H-O Oats add quick preparation—*and* the special taste-appeal of *pan-toasted* flavor. Cooked slowly and evenly over the dry heat of open fires, they have a distinctive, delicious flavor and an appetite tempting aroma. They make an instant hit with adult and child alike.

Try H-O Oats yourself. Notice the lighter, creamier oatmeal they make. Taste the difference between these and the usual oats. You'll see how easy it is to provide a quick breakfast which is both taste-appealing and nourishing at the same time.

* Oatmeal leads all other *whole grain* cereals in proteins. Oatmeal supplies 64 grams of proteins per pound.

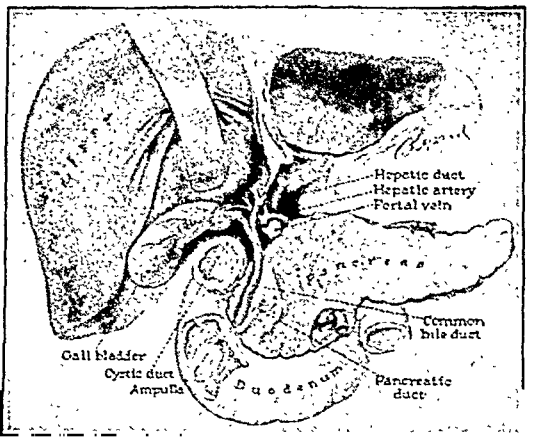


* Oatmeal leads all other cereals in food-energy. Oatmeal supplies 1,720 calories per pound.

* Oatmeal leads all other cereals in fat content. Oatmeal supplies 7.4%

Besides generous supplies of Vitamin B_1, niacin and nutritional iron

H-O OATS . . . FOR *FLAVOR!*



H-O Oats are slowly and gently *pan-toasted*—cooked over dry heat that leaves in all the concentrated fluffy oat goodness. Result? *Flavor!* Wonderful flavor made *even more attractive* by precision cutting for fine, even texture and lighter, creamier oatmeal. H-O Oats do taste different. *Deliciously different.* Try 'em yourself—you'll agree.

When Liver Function is Affected

SORPARIN

(EXT. SORBUS AUCUPARIA "McNEIL")

The wide field of usefulness for Sorparin includes all cases in which the function of the liver is affected—such as in administration of arsenicals, hemorrhage, surgery, jaundice conditions and chronic infections.

Sorparin acts on the liver cells, keeping them active to sustain the prothrombin level. It may be given routinely in all cases of biliary surgery since there are no untoward effects connected with Sorparin administration.

Sorparin is non-toxic, non-kinetic. It is absorbed and utilized in the absence of bile, and may be used concurrently with hydrochloric acid, sedatives or antispasmodics.

Supplied in tablets, each containing 3 gr. Sorparin

Bottles of 100, 500 and 1,000

McNeil Laboratories

Today—NESTLÉ'S Lion Brand Milk has a NEW LABEL . . . and a great new value!

400 UNITS OF VITAMIN D_3*

UNDER THIS NEW LABEL
—this new, improved milk replaces NESTLÉS Lion Brand

Today—to meet a recognized need—Nestlé's has produced an improved evaporated milk with *greatly increased Vitamin D.*

*25 USP units of IRRADIATED 7-DEHYDROCHOLESTEROL have been added to each fluid ounce—so that this *new* Nestlé's Milk supplies 400 USP UNITS OF VITAMIN D_3 per reconstituted quart.

This improved product is now on grocers' shelves under the *new label* (shown above). The name Nestlé's on this label is, *as always,* your guarantee that there's no finer evaporated milk. *Fortification with Vitamin D_3 does not alter this milk's flavor or destroy any of its natural vitamins.*

So the extra advantages of NESTLÉS Evaporated Milk will be available to everyone —despite the increase in Vitamin D, there has been *no increase in price.*

No feeding instructions furnished to the laity.

FEVER REDUCTION

Reduction of merely one degree in temperature can frequently make the difference between a febrile patient's comfort and misery. Effective antipyresis is obtainable by the administration of 'Tabloid' 'Empirin' Compound.

The synergistic action of the acetophenetidin and acetylsalicylic acid helps to reduce the elevated temperature. The headache and malaise which often accompany fever are usually relieved.

Each product contains acetophenetidin gr. 2½ (0.162 gm.), caffeine gr. ½ (0.032 gm.), acetylsalicylic acid gr. 3½ (0.227 gm.). Also 'Tabloid' 'Empirin' Compound with Codeine Phosphate, gr. ⅛, gr. ¼, and gr. ½.

'Tabloid' and 'Empirin' are Registered Trademarks

BURROUGHS WELLCOME & CO. (U. S. A.) INC.

'TABLOID' *Empirin* COMPOUND

Bottles of 100 and 500

Aminoids

REG. U.S. PAT. OFF.

A PROTEIN HYDROLYSATE PRODUCT

For ORAL ADMINISTRATION

Aminoids* is a mixture of amino acids and peptides, derived from Beef, Wheat, Milk and Yeast, with carbohydrates added. In the manufacturing process these protein foods are broken down by enzymes simulating the normal action of the human digestive tract.

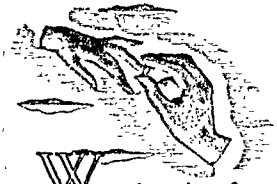
Aminoids supplements the protein intake of the diet . . . decreases the work required of the digestive organs . . . provides dietary nitrogen available for rapid assimilation . . . supplies the amino acids present in Beef, Wheat, Milk and Yeast.

Aminoids is indicated in pregnancy and lactation—pre and post-operative care—burns—ulcers—anemia—nutritional edema—nephrosis.

Aminoids is further indicated whenever the protein intake or utilization is insufficient as suggested by loss of weight—dietary history—albuminuria—impaired digestion, as in: Achlorhydria or hypochlorhydria—achylia gastrica—achylia pancreatica.

Aminoids may be taken in hot or cold liquids—water, milk, fruit juices, etc.

One tablespoonful of Aminoids T. I. D. supplies nitrogen equivalent to approximately 12 gm. of protein, as hydrolysate.



Dosage may be adjusted to meet the patient's requirements. Supplied in granular form in bottles containing six ounces.

ACCEPTED AMERICAN MEDICAL ASSN

The name Aminoids is the registered trade mark of The Arlington Chemical Company.

FACTS ABOUT NEO-SYNEPHRINE SULFATHIAZOLATE

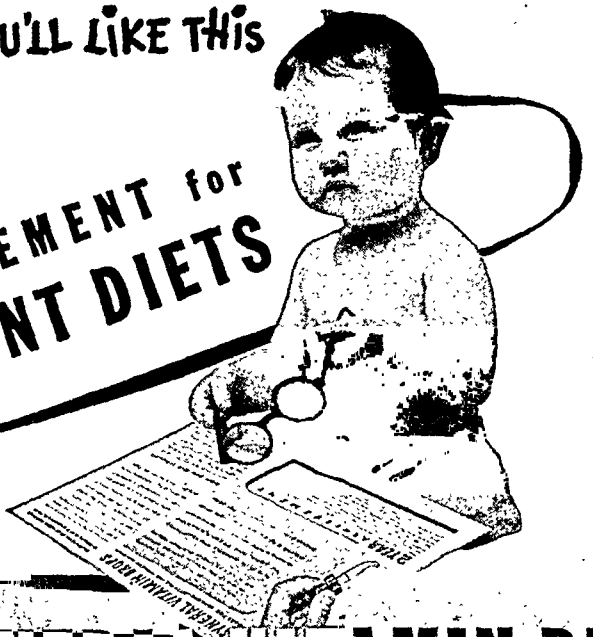
CHEMICAL UNION adds to Neo-Synephrine *the antibacterial activity of sulfathiazole* providing ample bacteriostasis with a minimal amount of sulfathiazole.

FULL EFFECTIVENESS of Neo-Synephrine is retained and continues undiminished—even on repeated use.

WELL TOLERATED locally, the isotonic solution is non-irritating to nasal mucosa and does not appreciably alter normal ciliary activity.

FREEDOM from side effects widens the field of usefulness. No wakefulness or other stimulation of the central nervous system has been reported.

INDICATED for decongestive effects and possibly bacteriostatic influence in combating secondary invaders accompanying common colds and sinusitis.



ADMINISTRATION may be by dropper, spray, or tampon.

DOCTOR, YOU'LL LIKE THIS

new SUPPLEMENT for INFANT DIETS

VI-SYNERAL VITAMIN DROPS

TWO YEARS' RESEARCH ACHIEVEMENT

A stable, comprehensive, non-alcoholic, multi-vitamin preparation

Each 0.6 cc. (as marked on dropper) provides . . .

Vitamin A	4000 U.S.P. Units
Vitamin B$_1$	1 Milligram
Vitamin B$_2$	0.4 Milligram
Niacinamide	4 Milligrams
Vitamin C	30 Milligrams
Vitamin D	570 U.S.P. Units

CONTAINS NO ALCOHOL

In 15 cc. and 45 cc. bottles, with marked dropper.

A MODERN FORMULA

Built on Newer Concepts of Infant Nutrition

Milk, both human's and cow's, fails to furnish optimum levels of all needed vitamins. Most infants, reports one prominent pediatrician (J.A.M.A. 120:12, p. 193), can benefit from supplementary supplies of Vitamins B$_1$, C, D, Niacin and possibly other B Complex factors . . . as milk, *at best*, furnishes only the bare minimum of these nutritional essentials.

VI-SYNERAL VITAMIN DROPS help to assure an optimum vitamin intake for infants—at a surprisingly low cost of about 4c per day. The Drops are readily accepted and well tolerated even by very young infants, also suitable for children and adults. Mix perfectly with milk or formula, fruit juices, soups, cereals, puddings.

- **Liberal potencies**
- **Contain no alcohol**
- **Vitamins are stable**
- **Economical**
- **Do not affect taste of foods**

Sample and literature upon request.

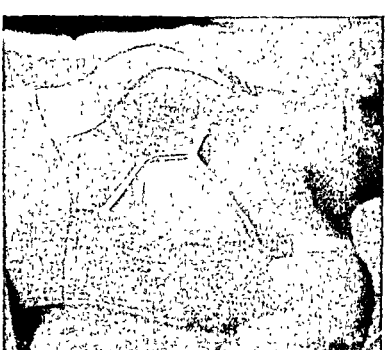
SPENCER BREAST SUPPORTS
FOR PRE-NATAL AND NURSING

Spencer Maternity Breast Support

Spencer Nursing Breast Support



Each Spencer Breast Support for pre-natal wear, like *all* Spencer Supports, is *individually designed* for the one patient who is to wear it, to lift and hold breasts in natural, healthful position, without compression.

It improves circulation—protects delicate inner tissues—helps prevent outer skin from stretching and breaking—aids breathing—improves appearance—encourages erect posture. Easily adjustable to increasing development.

Painful engorged breasts are often relieved by a Spencer, as it allows veins to empty easily. (A further advantage is gained later in increased milk supply from equalization of circulation during pregnancy.)

Guards Against Caking and Abscessing

The Spencer Breast Support for nursing mothers provides protection against caking and abscessing. Closes in front for nursing convenience.

Spencer Sleeping Breast Support

Spencer Sleeping Supports

are prescribed to continue day-time treatment during night hours. Protects breasts against crushing—aids breathing.

For service look in telephone book under Spencer corsetiere or write direct to us.

Preoperative Calm

ALTHOUGH many of the derivatives of barbituric acid have a generic resemblance in their principal action, there are significant differences which establish certain compounds in special clinical fields. For example, 'Sodium Amytal' (Sodium Iso-amyl Ethyl Barbiturate, Lilly), while frequently prescribed for insomnia, has been found particularly useful as a preanesthetic hypnotic. Given preoperatively it serves to allay fear and apprehension, improves the patient's mental attitude, thus facilitating surgical procedure. 'Sodium Amytal' is also widely employed in obstetrics. In recommended dosage it is capable of producing amnesia without prolonging dilatation of the cervix or interfering with the strength or frequency of uterine contractions.

Editorial

Nurses for the Armed Forces

Procurement of nurses for the armed forces in World War II has been difficult On December 19, 1944, Walter Lippmann, in the *Herald Tribune*, says of the present nursing shortage

"The last thing our people will put up with is that sick and wounded American soldiers should suffer because the Army cannot find enough women to nurse them Yet I am reporting only the stark truth, which is well known to the Army and to the leaders of the medical profession, when I say that in military hospitals at home and abroad our men are not receiving the nursing care they must have, and that with casualties increasing in number and in seriousness, this will mean for many of the men brought in from the battlefields that their recovery is delayed, and even jeopardized

"No one will question this statement So great is the shortage of women who are volunteering to nurse the sick and wounded that the Army has had twice to lower its own standard of nursing care In 1941 the standard called for 120 nurses and 500 enlisted men in each general military hospital of 1,000 beds

"By 1942 the Army had had to reduce the number of nurses to 105 Today in 1944, when our casualties are mounting, the Army has been driven to reduce its theoretical standard to 83 nurses and 450 enlisted men

"Instead of one nurse to eight beds the Army has had to come down to asking (though it is not getting) one nurse to twelve beds That this is a low standard is obvious when we realize that in civilian hospitals a ratio of one nurse to four or five patients is considered just barely sufficient"

This situation is of interest to physicians Most of us have believed, because we have been told on what we considered good authority, that nurses would be increasingly available to the armed services as a result of the nurse procurement program and the cadet nurse training schedule

As of November 15, 1944, 34,000 nurses have been classified in New York State [1] As of September 1, 1944, 12,554 student nurses are enrolled in New York State schools of nursing this year as compared with 8,826 in 1941.

In the June 1, 1944, JOURNAL we reviewed the nurse procurement program for the first

half of 1944.[2] At that time we were informed that the "State's reserve of 5,206 'available' nurses should be ample to provide the 1,328 necessary to complete the quota for the first half year without unduly depleting nursing service for the civilian hospitals."

We are further informed[1] that "New York State is asked to supply 827 nurses to the Army and Navy by December 31, 1944. That need is immediate and urgent."

Mr. Lippmann writes further:

"But even this standard to which the Army has been reduced is not being met. To meet it the Army Nurse Corps should now have 50,000 nurses. In fact it has 41,500. Instead of a ratio—low enough in all conscience—of one to twelve, the average in fact in continental United States is now one to twenty-two. . . . .

"There are plenty of women in the United States who are already trained nurses. There are plenty of trained nurse's aides. There are women who are being trained as nurses and more can be trained as nurse's aides. The problem is soluble. But it is not being solved and there is no prospect that it is going to be solved by issuing appeals to the nurses to enlist in the Army. The problem can be solved only if the American people understand it, and then make up their minds to see that it is solved. This will demand very plain speaking.

"About two months ago there were in the United States some 27,000 nurses who were declared to be not engaged in essential nursing in civil life, and therefore eligible for the Army if they could pass the physical and other tests. The decision about who was essential was not made in Washington; it was made by responsible medical and nursing associations in each community, and we are entitled to assume that they took no unnecessary risks with the health of their own communities. The Army made no appeal to each of these 27,000 women. The Army received 760 answers, and 227 signed up. Out of the whole 27,000 the Army got less new recruits than there were nurses who for various good reasons had to leave the nurse corps during the month of November alone."

Mr. Lippmann is doing a major service to the Nation by calling attention to the needs of the armed forces for nursing service. If he is correctly informed, it seems to us to be the duty of every physician in this State, and of every county medical society, and of the woman's auxiliary of every county society where such exist, to lend aid to the local Red Cross Recruitment Committee and to find out the follow-up done by them on nurses in Class I.

"Women are not subject to the draft. They cannot be forced to serve. Moreover, unlike workers in war industries, they cannot be paid to serve by giving them high wages. They are neither compelled nor induced; they have neither a legal duty nor a pecuniary reward. This means that each woman who volunteers must do so because she has a much higher sense of public duty than we expect or find in the general average of this or any other nation.

"But it means also that each trained nurse who has to make the choice of enlisting is in fact offered a strong inducement not to enlist. If she stays in civilian nursing, she does not have to place herself under Army discipline, or go away from home, or face the discomforts and risks of service in the theaters of war. She can make a great deal more money because the civilian patients have a lot of money, and are willing to pay high prices for special private nursing. Finally, she is subject to considerable pressure of one kind and another to stay where she is, and so to protect her job and her career after the war.

"Women, though they are fit and without family responsibilities, have no national duty under the law to serve their country; there are combined financial and institutional and what might be called professional trade-union pressures upon women to prefer civilian to military service. The result is not only to discourage enlistment in the nurse corps, but to create inertia and resistance in the face of the many practical efforts being made to enlarge the supply of women who can do some nursing, be it as nurse's aides or Wacs. Only an aroused and informed public opinion, focused as it may be by a Congressional inquiry, can break this logjam in the recruitment of women to nurse the sick and wounded soldiers of the American Army."

Speculation as to the causes of the nurse shortage is of little present help to the armed services, to the Veterans' administration, and to the continental military hospital bases. It does not seem possible that present necessities for nursing service could have been seriously underestimated by the Surgeons General. Nor do we think that American women will fail the armed forces in their desperate hour of need, if the serious necessity is made plain to them, as Mr. Lippmann and others are attempting to do.

At the same time it is certainly permissible to ask why the large body of possible material classed as 4F has not been utilized where practicable as male ward attendants.

Many in this category have been rejected for military service for defects which would not seriously interfere with their perform-

ance of duty as ward attendants. Many would doubtless welcome the opportunity.

Recheck of draft registrants classified as 4F is now under way. If twenty weeks' training would qualify some of them as ward attendants, such procedure would seem to be worth considering.

"The record of the Medical Corps thus far is brilliant—measured by the lives it has saved, by the numbers of men who have been spared the crippling effects of their wounds, by the number of men returned to good health who in other wars would have become lifelong invalids.

"But I am saying, not on my own authority, of course, but on that of the responsible commanders, that this record cannot be sustained if the work of the surgeons and doctors and of the devoted Army nurses and corpsmen is not reinforced at once by more women—by women who know how to nurse the sick, and who by their presence, and because they are women moving about among men who are in pain, in fever, in low spirits, and are lonely, evoke the will to live and to recover."

Let us have the women nurses by all means, and as rapidly as possible. But let us not overlook any possible assistance for the seriously overworked men and women who are now carrying on as medical corpsmen and nurses.

The Bureau of Medical Care Insurance

The JOURNAL is pleased to announce that as of February 1, 1945, Mr. George P. Farrell, of Buffalo, will commence work for the Medical Society of the State of New York as Director, Bureau of Medical Care Insurance.

Mr. Farrell will have his offices at 292 Madison Avenue, New York City.

Mr. Farrell was born at Henrietta, New York, a short distance from Rochester. On completion of high school, he commenced a special educational course in life underwriting with the Connecticut Mutual Life Insurance Company of Hartford. He then entered the life insurance business with the Earl F. Colborn Agency in Rochester, New York, at the age of 20. With this agency his work was primarily concerned with estate planning. In 1925 he completed one of the first courses offered for certified life underwriters given by Columbia University. On completion of this special study he served for six years as a member of the Board of Directors of the Rochester Life Underwriters' Association.

In 1937, after leaving the Colborn Agency in November, Mr. Farrell associated himself with the Hospital Service Corporation of Western New York.

His duties were in the capacity of Supervisor of Enrollment.

In the early part of 1940, the Western New York Medical Plan was offered through the administration of the Hospital Service Corporation of Western New York on a service basis within certain income limitations. In 1943, the change was made from a service to an indemnity contract. The reason for this change, based on practical experience with the service feature, arose because of difficulties encountered from an enrollment and service standpoint on service contracts. It has been the experience of the Western New York Medical Plan after about two years of experiment with the indemnity form of contract, that it has been possible to eliminate a great deal of the misunderstanding which previously occurred between doctor and patient, when the service form of contract was in force.

With this background of experience, the new Director, Bureau of Medical Care Insurance, should be well equipped and prepared to carry forward the practical business of the establishment on a broad base of prepaid medical care insurance in this State.

We welcome Mr. Farrell and wish all success to the new Bureau.

An Adequate Diet, I*

When taking a history a physician often asks, "Is your diet adequate?" The patient may respond, "Yes, it is," and too frequently the discussion of diet and nutrition is ended.

An adequate diet must contain a sufficient number of calories. Because the caloric needs vary according to age, sex, and activity, the physician must be familiar not only with the caloric requirement of his patient, but also with the optimum proportion of the different foodstuffs, namely, protein, fat, and carbohydrate. He must also know the minimum mineral constituents necessary. And, last, he must know the vitamin requirement.

The minimum proportion of these calories which should be supplied as protein is about 10 per cent of the total calories, which figure is fixed by the body's specific need for this nutrient. The proportion which should be supplied as fat is a physiologic question of special importance economically because carbohydrates are the cheaper and more abundant source of energy. Both these foods are "protein sparers"; that is, carbohydrates and fats, by furnishing the calories necessary for body energy, allow the nitrogen of protein to be used for the synthesis of the amino acids required for building body proteins that replace wear and tear. In this role, carbohydrates are more directly useful than fats, for they maintain glucose blood level and unite with the nitrogen in the synthesis of amino acids. The role of fat in these functions is negligible. At the present time, little physiologic information is available as to just what the fat content of an adequate diet should be.

The body is unable to synthesize from carbohydrates or fats, in general, certain fatty acids essential for growth, notably linoleic and linolenic, as judged from studies with rats. These fatty acids must be supplied in the diet quantitatively to the extent of 1 per cent of the total calories. Fortunately, these essential acids are widely distributed and are found in such food fats as lard, soybean oil, cottonseed oil, and peanut oil. Unquestionably, diets with a liberal amount of fat are much more palatable and, because of this, are more likely to be adequately consumed than bulky diets. Because fat has a heat value which is over twice that of carbohydrates, it reduces the amount of food required to meet caloric needs. This is of special importance when the caloric requirements are high, as for persons at hard work. Fat, because of its slow passage through the stomach, delays hunger pains and therefore has a satiety value.

The Food and Nutrition Board of the National Research Council[1,2] has recommended that the diet in general should contain a minimum of 20 to 25 per cent of its calories in the form of fat; and that for children and persons at hard work, the desirable range should be 30 to 35 per cent. These recommendations appear to be backed more on general information and observations than on quantitative data. They pertain to diet requirements for Western peoples only, for the requirements of Eastern peoples, who now eat less than 10 per cent of fat in their diet, are more obscure.

Because calories produced from animal fat require more land and labor than those derived from vegetable fat, the latter source is a cheaper one. The relative value in the diet of these sources is an important question both economically and physiologically. At the present time there is no physiologic evidence which justifies any generalization that animal fats are nutritionally superior to vegetable fats. Fortunately, the essential fatty acids are found in both sources. The amount contained varies according to specific source rather than according to class.

That some fats are nutritionally more valuable because of their content of fat-soluble vitamin A is known, the most notable example being butter. There are, however, many other food sources of this vitamin, namely, milk, green leafy vegetables, carrots, and oleomargarine fortified with vitamin A. The important physiologic question is whether the unique fatty-acid distribution in butter gives it a physiologic advantage over other fats. Despite many studies, science has not been able to demonstrate any such advantage in a mixed diet.

* This is the second editorial in a series on "The Facts of Nutrition." The first appeared in the January 1 issue.

THE EPIDEMIOLOGY OF POLIOMYELITIS*

JAMES E. PERKINS, M.D., Albany, New York

I HAVE been asked to talk upon the epidemiology of poliomyelitis, that is, the community characteristics of the disease in contrast with its characteristics as it occurs in the individual patient. The epidemiology of poliomyelitis consists in the study of the disease according to age groups, sex, geographic pattern, seasonal and annual cycles, and so on. However, as the late Dr. Wade Hampton Frost commented, "Epidemiology .... is something more than the total of its established facts. It includes their orderly arrangement into chains of inference which extend .... beyond the bounds of direct observation."[1] Rather than merely present a series of dry statistics covering all phases of poliomyelitis, therefore, I hope to present selected epidemiologic data in a certain order which I think throws light on the manner in which poliomyelitis usually is spread.

Our status with regard to poliomyelitis is similar to that of about eighty years ago with regard to cholera and typhoid fever. At that time the science of bacteriology had not been established and there were many divergent and strongly acclaimed theories as to the manner in which cholera and typhoid fever were being spread. Certain physicians[2,3] of that time, however, studied intensively the patterns of spread of these diseases. They concluded that cholera and typhoid fever were being caused for the most part by the drinking of water polluted by the excreta of infected individuals. These conclusions were entirely confirmed later when the development of the science of bacteriology resulted in the identification of the specific causative micro-organisms.

As to poliomyelitis, since the causative agent is a filterable virus, and because there is no cheap, small laboratory animal which may be infected *directly* with secretions or tissue from human beings, unusual difficulties have been encountered in direct laboratory experimentation, so that at the present time we must still depend to a large extent upon epidemiologic evidence to give us information as to the usual manner of transmission.

It is obviously important that we do have a reasonably accurate conception of the manner of transmission if we are to give intelligent advice to the public. Newspaper clippings which have come to my desk during the summer indicate greatly diverging views expressed by various physicians throughout the state as to the way in which poliomyelitis is spread. I do not wish to give any impression of ridiculing the opinions which have been given. They were expressed by intelligent physicians who were giving advice on the basis of observations they had made or on their interpretation of what they had seen in the literature. However, since the average physician sees only relatively few cases of poliomyelitis even at times of epidemics, his observations are necessarily limited, and it is possible that these limited observations may lead at times to incorrect inferences with regard to the disease as a whole.

Study of the statistical data on poliomyelitis received in the New York State Health Department together with certain rather unusual opportunities to study in the field the pattern formed by acute cases of the disease[4] have led me to some rather definite conclusions concerning the usual manner of spread of poliomyelitis. Please note I stress the word "usual." I see no reason why in poliomyelitis, as in certain other communicable diseases, spread may not occur occasionally in more than one way, and as I shall indicate later, there is evidence that at times unusual modes of transmission apparently have occurred.

Susceptibility

So as to have an orderly presentation, let us recall that for a human case of communicable disease to occur, there must be (1) a susceptible person to acquire the disease, (2) a reservoir of infection, and (3) some means of transmitting the infection from the reservoir to the susceptible person. As to the first factor, susceptibility, it must be clearly kept in mind that in poliomyelitis, paralysis is a relatively rare complication of the disease. I cannot stress this point *too strongly, since it is essential to a clear understanding* of the epidemiology of poliomyelitis. This has been adequately demonstrated through clinical observation and confirmed by laboratory studies. In some recent studies which the New York State Department of Health[5,6,7] conducted in two rural communities in which cases of paralytic poliomyelitis had occurred, we found by virus studies of stools that there were many more

* Presented in abbreviated and modified form at teaching days on poliomyelitis held in Elmira, Buffalo, Rochester, Syracuse, Oneonta, Mineola, Poughkeepsie, Plattsburg, and Alexandria Bay during July and August, 1944, under the auspices of the various county medical societies, the Medical Society of the State of New York, and the New York State Department of Health.

Director, Division of Communicable Diseases, State Health Department, Albany, New York.

infected individuals in the area than those who went on to clinically recognizable poliomyelitis, and with a concentration of these infected individuals among those with a history of association with the paralytic cases.

I shall not attempt in this discussion to consider in detail the possible factors responsible for development of the paralytic form of the disease in the occasional child. I merely wish to point out that everyone is in agreement that the number of nonparalyzed patients with the disease markedly exceeds the number of paralytic patients. In spite of this, observers often seem to forget this well-established fact in stressing certain so-called "mysterious" aspects of the disease. Often-quoted statements, such as, "Only one case occurs in a family," and "One can never trace one case to another," are the result of omitting from consideration this fact of the prevalence of nonparalyzed cases.

Another epidemiologic observation in connection with this matter of susceptibility is the absence of cases in a community for a period of years following an epidemic. This is similar to the observed facts in measles and other diseases with a high rate of infection and with a high degree of immunity resulting from infection. In other words, the forest fire consumes the dry wood, and one must wait for an additional accumulation before another conflagration is possible. This brings up another often-quoted "mysterious" observation in poliomyelitis; namely, the way in which the disease will fail to invade a certain community in a given outbreak. Not infrequently one finds that the community in question had an outbreak within the previous few years. The phenomenon then becomes about as mysterious as observing a forest fire fail to invade a swampy area.

Reservoir of Infection

As to the reservoir of infection, there is no definite evidence that there is an animal reservoir other than man himself. Furthermore, the epidemiology of the disease does not indicate that any animal or insect reservoir of infection is actually necessary any more than such a reservoir is necessary for the perpetuation of measles.

It may be pertinent at this time to digress for a moment to consider what human secretions or excretions are infectious and the usual portal of entry. The relatively recent confirmation[8,9] of the presence of the virus in large quantities and for long periods of time in the stools of infected individuals is an important observation, but this observation alone does not justify the conclusion that the usual manner of spread is through the feces. It is readily possible to demonstrate tubercle bacilli in gastric contents and in feces; yet no one claims that tuberculosis is spread ordinarily via feces. On the other hand, the presence of poliomyelitis virus is also readily demonstrated in the pharyngeal mucosa and oropharyngeal secretions[10,11]—and let me point out parenthetically that the pharynx is part of the gastrointestinal tract, as well as the respiratory tract. I should state that when I use the term "respiratory-spread," I mean the manner of acquiring infection; that is, through droplets or droplet nuclei. The actual portal of entry in poliomyelitis, I suspect, is usually the pharnygeal mucosa, although it may at times be lower in the gastrointestinal tract.

A recently published article bears on this point. Faber, Silverberg, and Dong[12] present data indicating that four Cynomolgus monkeys were infected through inhaling apparently true air-borne droplet nuclei from virus suspensions sprayed into the air even though the olfactory nerve route had been blocked. Histologic study revealed that in three cases invasion of the central nervous system probably had been by way of the afferent fibers of the trigeminal nerve into the Gasserian ganglion and thence to its central connections in the pons-medulla, and in the fourth case invasion had been by way of the sympathetic fibers of the nose or nasopharynx into the cervical sympathetic ganglia and thence into the uppermost levels of the thoracic cord. In one monkey the results were particularly clear-cut, and I quote from the comments concerning the results in this monkey:

> "Summary.—This is a particularly clear-cut example of entry of infection from the mucosa through the afferents of the fifth cranial nerve into one Gasserian ganglion with involvement of its central connections and spread to the lower brainstem and cord—no bulbar phenomena were noted, and the primary site of paralysis was in the legs—clear proof is presented that primary leg paralysis was not due to primary entry through the intestine....."

I hesitate to quote animal laboratory experiments because all too often in the past it has been found such studies were not applicable to the disease in human beings and they have led us astray at times rather than clarified things. I have in mind particularly the demonstration of the ease of infection of monkeys through gentle application of the virus to the nasal mucosa which seemed to agree so well with epidemiologic data, but upon histologic and virus examination in human cases it was found that the usual route of infection was *not* via the olfactory nerves. This observation in no way invalidated the unrelated epidemiologic data suggesting person-to-person spread in poliomyelitis. The carefully conducted epidemiologic studies of thirty years

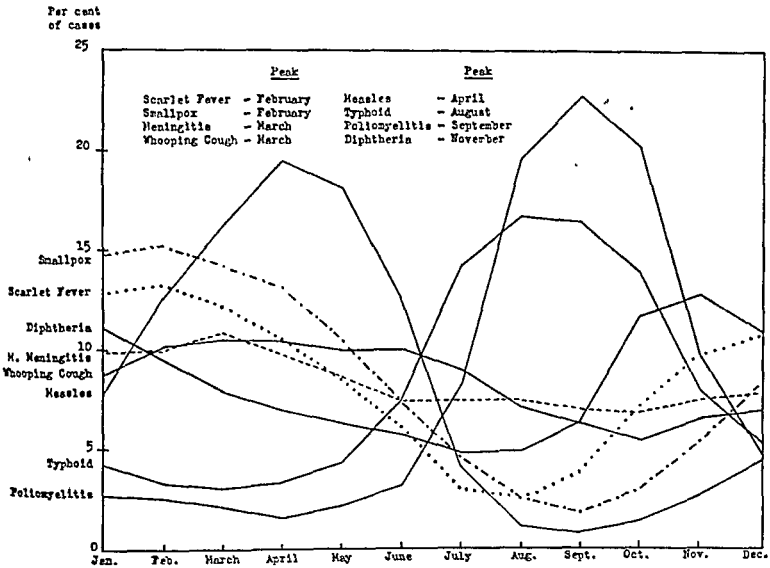

FIG. 1. Seasonal prevalence of certain communicable diseases from the report on communicable-disease control, White House Conference.[15]

(U. S. Registration Area 1921–1927, incl.)

ago, such as those by Frost,[13,14] are as significant today as they were when originally reported, and in my opinion are a much firmer foundation for the building of a conception as to the mode of transmission than more recent laboratory animal experiments of questionable interpretation in terms of human beings.

Mode of Infection

Insects.—Considering next the third factor, namely, the actual manner of transfer of infection from the reservoir to the susceptible individual, let us consider briefly insects, water, milk, and person-to-person contact. One very good reason that an insect vector has been considered strongly has been the well-known observation that the peak of poliomyelitis usually occurs in the summer when certain insects are prevalent. It must be stressed, however, that the mere prevalence of an infection in the summertime is not in itself a fact which excludes the possibility of spread through person-to-person contact. Every communicable disease has a seasonal variation in prevalence of infection[15] (Fig. 1). It is agreed by all physicians that diphtheria, scarlet fever, and measles are usually spread through person-to-person contact via the respiratory tract, and yet the usual peaks in these diseases are scattered throughout the seasons, with the peak in diphtheria in this latitude being in the late fall, that of scarlet fever in the winter, and measles in the spring. The interval between the peaks in diphtheria and measles, in fact, is greater than that between the peaks of poliomyelitis and diphtheria, or poliomyelitis and measles. The often-quoted statement that poliomyelitis disappears as soon as there is a frost is not an accurate statement. Although, in general, poliomyelitis is on the down-swing at the time cold weather sets in, there is no close correlation between temperature and prevalence of the disease, with epidemics frequently continuing well into cold weather.

Another basis for doubting the factor of an insect vector is through the comparison of the pattern of spread of poliomyelitis with the patterns in diseases in which we know that insect vectors are involved. Malaria, for example, is

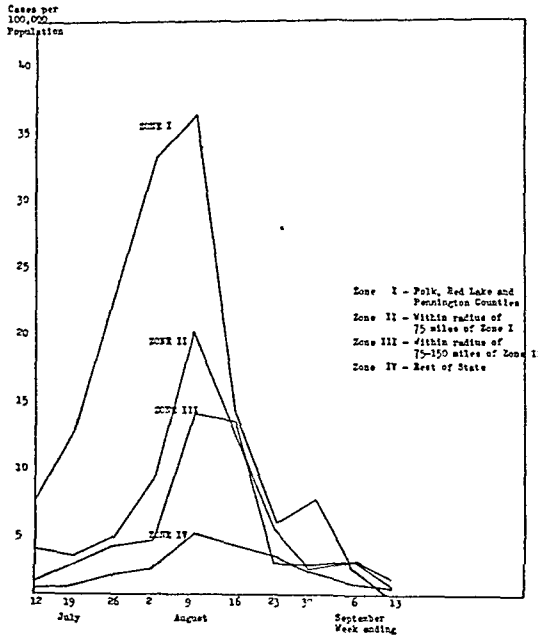

FIG. 2. Equine encephalitis cases in Minnesota in 1941.

very much of a rural disease in the United States; in endemic foci the malarial death rate in rural areas is several times that in the urban communities in those areas.[16] In poliomyelitis, although the rates are higher in rural areas, the difference between the rates in the largest communities and the very rural areas is such that one is hardly justified in calling it a disease of rural areas. Thus, for the twenty years 1920–1939 in upstate New York the average annual morbidity rate for places over 250,000 population was 7.0; places of 50,000 to 250,000 population, 8.4; places of 10,000 to 50,000 population, 8.9; places of 2,500 to 10,000 population, 9.4; and for places of under 2,500 population, 11.3. It was found that rates based on anything less than a ten-year period were unreliable, since statistics for shorter periods are usually dominated by one particular outbreak of extensive proportions and the rates by population groups are markedly affected according to the size of the community which was affected in that particular outbreak.

If one considers numbers of cases rather than rates, three fourths of all the cases reported from 1920–1939 occurred in places of 10,000 population or larger, which would not indicate that poliomyelitis is primarily a rural disease.

Two other diseases which we might compare with poliomyelitis are equine and St. Louis encephalitis, which have been shown to be spread by mosquitoes. These are predominantly rural diseases and occur principally in adults, in contrast with poliomyelitis. Following the very large 1941 outbreak of equine encephalitis in northwestern Minnesota, northeastern North Dakota, and that part of Canada immediately adjacent to these areas, in which there were hundreds of cases of equine encephalitis, we obtained the case reports for Minnesota by date of onset and locality from the Minnesota Health Department, and tried to demonstrate a radial manner of spread, with complete lack of success. There was a progressively lower attack rate as one proceeded from the central focus through concentric zones drawn around it, but in all zones, the peak occurred at the same time, instead of at a progressively later date as one proceeded peripherally from the focus (see Fig. 2). In other words, there was no evidence of peripheral spread but merely a variation in attack rates as one proceeded outward from the central focus.

As to flies, the demonstration of the presence of virus on flies which have been permitted to come in contact with human excreta certainly indicates a theoretic possibility that they may at times spread the disease, but it does not indicate necessarily that flies are the *usual* means by which the disease is spread. The marked reduction in the fly population in large cities (resulting from virtual elimination of horse-stables) and the elimination of privies in large cities (resulting in elimination of access by flies to poliomyelitis virus in human excreta) has not been followed by a reduction in the prevalence of poliomyelitis in these large cities, which would suggest that flies ordinarily are not very important in the transmission of the disease. In the recent large outbreak in Buffalo it is beyond my comprehension that flies have played any appreciable role in the spread of the disease in that city.

Water.—As to transmission through water, this has been covered so excellently by Dr. Kenneth F. Maxcy, professor of Epidemiology, Johns Hopkins School of Hygiene and Public Health, that I need only refer you to his article.[17] Suffice it to say at this time that in his intensive study of this possibility, Dr. Maxcy points out that from laboratory data it would seem to be a definite possibility that the disease might be spread in this manner. He then goes on to examine the evidence and finds none that it ever has been so transmitted. Outbreak after outbreak of typhoid fever, gastro-enteritis, and other illnesses have been shown conclusively to have been water-borne, but there is no outbreak on record in which the usual characteristics of a water-borne outbreak have been found, in spite of these poliomyelitis outbreaks having been studied intensively by well-qualified investigators

who have incriminated water supplies in other investigations conducted by them. Poliomyelitis outbreaks simply do not occur in explosive form, confined to the consumers of a given common water supply. It usually spreads peripherally from a focus in some locality, extending progressively outward, completely disregarding the boundaries of common water supplies. This, of course, does not rule out the possibility of an occasional household outbreak caused by a single polluted well, but if this happens with any frequency, one would expect, as in typhoid, that a similar situation would inevitably occur sooner or later in connection with a municipal water supply, which apparently has not been the case.

Milk.—As to milk, two outbreaks have been recognized in New York State in which it seems quite conclusive that raw milk was the means of transmission, one in 1916[18] and one in 1925,[19] involving only seven and eight cases, respectively. In each instance investigation revealed that an acute case of poliomyelitis had occurred shortly before the outbreak on the farm or dairy from which the raw milk came. Furthermore, there were certain flagrant violations of sanitation and hygiene in each instance so that there was ample opportunity for direct pollution of the milk to have occurred, and if milk transmitted the infection it probably merely served as a mechanical means of dissemination of an unusually heavy dosage of the virus. In spite of intensive investigation, no other outbreaks having the characteristics of a milk-borne affair have been recognized in this State, and, on the contrary, a wealth of evidence has been uncovered indicating that milk supplies are not involved ordinarily in the transmission.

Person-to-Person Contact.—Finally, let us consider transmission through person-to-person contact. Many of the statements which have been made thus far obviously indicate that poliomyelitis has many features in common with communicable diseases which are known to be so transmitted. Previous reference has been made to the radial spread of poliomyelitis, and Fig. 3 illustrates this phenomenon in the first cases I investigated in the southwestern corner of Minnesota in 1930. Each large division represents a county, and each small solid square a case of poliomyelitis by month of onset. The concentration of cases through July in the second county (Nobles) east of the corner in the lowest tier represents those in the village of Worthington, which served as the focus of dissemination in this outbreak.

Radial spread in poliomyelitis had been demonstrated many times before this, and it has been possible to demonstrate it repeatedly in New York State. In the current, 1944, outbreak, radial spread again seems to have occurred. There have been two principal foci: one in Erie County, and one in Steuben and Chemung counties combined. In Erie County the disease seemed to spread from the town of Eden northward (Lake Erie is a short distance west of the town) to Hamburg, to Lackawanna, and on to Buffalo. Interestingly and significantly, in this last outbreak in Buffalo cases seem to be concentrated in the outlying sections of the city, largely sparing the heavily populated central sections of the city which were principally attacked in the 1939 outbreak. In the Steuben-Chemung area, the disease spread across the State line from Tioga County in Pennsylvania, where an unusual number of cases (four) occurred scattered through the previous fall and winter in the hamlet of Knoxville and vicinity, flaring into an epidemic in the nearby village of Elkland and vicinity in May and June. The village of Addison just over the line in New York bore the brunt of the epidemic in that part of New York State. With a population of only 1,617 (1940 census) the village reported 16 cases with onsets from June 12 to July 26. The disease then fanned out peripherally, involving Corning, Elmira, and Hornell.

Radial spread in poliomyelitis is of interest for several reasons. The disease is on the wane in the central focus while it is still ascending in the outer concentric zones. These areas are so close together that, obviously, they are under the same climatic conditions, so that the decrease in the central zone cannot be explained by a change in weather conditions. The most obvious explanation is an exhaustion of susceptibles in the central focus, and it may be compared with a brush or grass fire, in which the blaze dies out in the center as it continues to flare up around the periphery.

As I have pointed out before, we were unable to demonstrate a similar phenomenon in connection with the epidemic of equine encephalitis in Minnesota in 1941. A similar picture may be obtained, however, by analyzing data for measles. Fig. 4 shows the spread of measles in Genesee County in 1939, together with the radial spread of poliomyelitis in the same county the same year. In the measles part of the chart, Zone I consists of the towns of Darien and Pembroke; Zone II, the adjacent towns of Alabama, Oakfield, Elba, Batavia, Alexander, and Bethany; and Zone III, the rest of the county.

We have been able to demonstrate this radial spread in measles elsewhere in the state and in other years. As a matter of fact, if one considers a complication of measles such as bronchopneumonia to represent a complication corresponding to paralysis in poliomyelitis, these [illegible] re

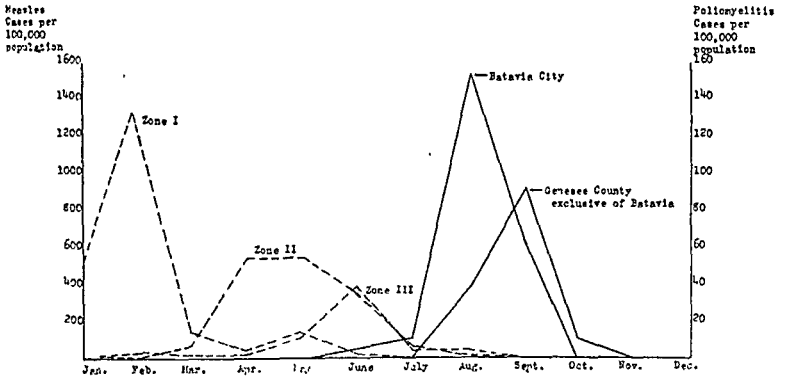

FIG. 4. Measles and poliomyelitis in Genesee County during 1939 Measles- - - - Poliomyelitis———

remarkably similar other than with regard to the time of year when the majority of cases occur.

Another similarity to measles besides radial spread is the general age distribution. Measles, to be sure, has more of a concentration of cases in the 5–9 age group than does poliomyelitis, but both are predominantly childhood diseases. Furthermore, in both diseases in individuals 10 years of age and over, there is a progressively increased morbidity rate as one proceeds from large cities to small cities, to villages, and, finally, to completely rural areas. This phenomenon, in fact, is noted in other respiratory-spread diseases in which the causative agent is widespread and a high degree of immunity results from an attack of the disease. It is generally considered to be caused by the fact that in smaller communities there is less contact between individuals, and one is more likely to first encounter a given pathogenic micro-organism at an older age.

These statistical observations, which indicate that poliomyelitis more closely follows the pattern of diseases known to be spread through person-to-person contact, suggest that the usual mode of transmission is by that means. In addition, many direct observations have been made which suggest the disease is so spread. It is rather surprising, in fact, how frequently one can trace the infection from one family to another provided one conducts an intensive investigation in a rural area where there are fewer contacts with unknown individuals than is the case in the city. I have made a number of such observations,[4] and one of these in the 1930 Minnesota outbreak is of special significance, in my opinion.

Prior to the reporting of poliomyelitis in twin boys, aged 19 months, from Osceola Township, Renville County, essentially all of the cases had been confined to the southwestern corner of Minnesota. These two cases, however, were distinctly beyond the focus of that time. In spite of questioning and cross-examining, I could not shake the mother from her assertion that the twins had not been away from the community at any time during the entire summer and that they had had no visitors. I recalled, however, that in a prior investigation of cases in a family in the village of Holland (in the focus), I had secured a history to the effect that after known exposure to poliomyelitis, the family had gone on an automobile trip toward the center of the state, and that while away on this visit, one of the children, a boy, A. N., aged 9, had become ill on July 20, causing the family to return home. This child developed a typical paralytic case of poliomyelitis. I therefore drove the 109 miles back to Holland Village and reinterviewed this family, inquiring exactly as to where they had been on their auto trip. I shall never forget the thrill I received as the mother gave me directions to reach the farm where they visited, for in telling me to take a certain new highway, fork onto the old highway at a certain point, turn left at the end of this road where a meeting house was located, et cetera, she was giving me directions leading directly to the farm of the twins! But she stopped one farm this side. I then dashed back to the farm where this family had visited and learned that two children on the farm, a girl, E. B., aged eight, and a boy, R. B., aged seven, had become ill about July 25, after the visitors from Holland Village had left. Their younger sister, G. B., aged three, who had been away on a visit, was brought back to the farm just prior to the development of the illnesses in her brother and sister, and about August 1, she, too, became ill. All three of the illnesses were called by the family "summer flu," but the boy, R. B., gave

a history of having difficulty in walking for a period following his illness, and I have classified his case as one of paralytic poliomyelitis. The twins had been brought over by their mother to this neighboring farm to visit, and had played with G. B., right at the time of her illness. About a week later the twins became ill, both on the same day, August 7. One developed paralysis of the left leg, and the other paralysis of the right deltoid muscle.

This series is of particular interest because if one investigator had not investigated both the Holland Village family and the Renville County cases and had not obtained and remembered the history of an automobile trip by the former to the general vicinity of the latter, the connection between the two would not have been discovered. If the association had not been determined, these cases in the twins might very well have been held up as examples of poliomyelitis suddenly appearing in a community in which there had been no poliomyelitis previously, and occurring on an isolated farm among children who had not been away all summer and who had had no visitors.

From the above and other observations, I feel that the theory to the effect that the usual mode of transmission in poliomyelitis is through person-to-person contact checks better with all of the epidemiologic observations than any other theory. I feel, therefore, that any advice which is given at present to the public should be consistent with this conception as to manner of spread.

Control Measures

This brings one to the question of control. Offhand one might be inclined to say that upon the theory of person-to-person spread the obvious procedure to follow upon the appearance of the disease in a community would be to rigidly restrict the mingling of people, especially children, and to rigidly isolate every reported case until noninfectious, as well as to quarantine all contacts. Upon more sober reflection, however, it will be realized there are two facts which militate against the effectiveness of such a program; namely, (1) that ordinarily the only cases reported to the health department are definitely paralyzed cases, which represent only a small fraction of the total infected individuals in the community capable of spreading the infection, and (2) by the time the case is reported, the patient usually has had ample opportunity to pass the infection to others. This latter point hinges upon whether the oropharyngeal secretions or the feces are the chief sources of infection. If feces are of major importance, which I question, isolation is impractical since from experimental evidence we know the feces contain the virus for long periods of time and a corresponding period of isolation would not be feasible. Furthermore, there is no practical, simple laboratory examination available for the routine determination of the termination of the presence of virus in the feces. If the oropharyngeal secretions are principally of importance, which I believe to be the case, there is epidemiologic evidence[4,20] that the patient is infectious for a relatively short period of time, principally at the time of or just before the first appearance of symptoms, when diagnosis is difficult or impossible.

Poliomyelitis, then, appears to fall into the respiratory-spread group of diseases represented by such diseases as chickenpox, smallpox, diphtheria, measles, whooping cough, meningococcal meningitis, and pneumonia. In none of the diseases in this group have public-health authorities been successful in controlling the spread of infection except in those instances in which an effective means of active immunization has been developed. The tendency of health departments in the diseases of this group for which there has not been devised as yet an effective means of active immunization has been to discard rigid isolation and quarantine requirements, which have been found to be ineffective in controlling spread and a waste of the valuable time of health officers and public-health nurses, in favor of concentrating upon those aspects of these diseases in which something may be accomplished, such as passive immunization of the infant exposed to measles, and prompt and adequate medical care of the patient developing meningococcal meningitis or pneumococcal pneumonia.

The Public Health Council is to be congratulated on its recent modification of the Sanitary Code restrictions in this disease, confining them to isolation of the patient during the febrile stage. This probably covers the period of greatest infectiousness, and brings the restrictions in this disease into line with those applying to the other diseases in this group. It is more important in poliomyelitis to put emphasis upon prompt and adequate medical and nursing care of the individual developing evidence of involvement of the nervous system than to engage in ritualistic quarantine procedures merely to impress the public that the health department is "doing something."

The consideration of quarantine brings up the question of the advisability of closing theaters, churches, and places of business in an outbreak. I feel that this definitely is not the procedure to be followed. It has been attempted in communities from time to time during the past thirty years, and in each instance has been found to be of no avail in checking the spread of the infection, although very effective in disrupting the entire social and economic life of the community. It may be discreet to discontinue temporarily com-

munity-operated places of congregation of children, such as schools and swimming pools, even though any effect on an outbreak by such a procedure is doubtful. For the most part responsibility for restriction of the activities of children should be placed upon the parents.

I think it is sound, in the presence of an epidemic, to advise parents to keep their children [illegible] children in so far as [illegible] avoid contact with [illegible] symptoms of illness whatever, regardless of the apparent diagnosis. This latter is good advice anyway, since in practically every communicable disease the patient is most infectious during the first stages when the symptoms have not developed to a point where a diagnosis is feasible. As a matter of fact, in poliomyelitis this advice with regard to avoiding crowds and ill individuals may be more logical from the standpoint of reducing dosage rather than preventing infection altogether. This point is admittedly upon a theoretical basis, but has some foundation, since in the experimental disease the outcome within limits varies with the amount of virus given. It will be extremely difficult, if not impossible, to so isolate a child as to eliminate every possibility of having the virus brought to him. From a cold scientific standpoint, there may be some doubt, in fact, as in measles, as to the wisdom of postponing to adulthood one's first encounter with the virus even if it were possible to do so. The case-fatality rate definitely increases with age. Perhaps it is better to attempt to reduce the likelihood of excessive dosage and to have the child in as good condition as possible to emerge unscathed from the encounter, which brings me to my next bit of advice to parents.

When poliomyelitis is prevalent in a community (which is another way of saying that at that time children in that community are more likely to have their first contact with the virus) parents should attempt to see that the children do not become overfatigued, since there is evidence that fatigue may be of importance in determining the extent of paralysis. Furthermore, clinicians seem in agreement that often the worst cases of paralysis develop in individuals who, in spite of being ill, continue excessive activities until they finally are so incapacitated they can carry on no longer.

Upon experimental evidence, chilling should also be avoided,[21] since it, too, possibly may predispose to the development of more severe paralysis than might otherwise be the case.

Another point is that there is sufficient evidence of the association of the serious bulbar type of poliomyelitis with tonsillectomy[22,23] to justify recommending that in an area in which poliomyelitis is occurring in epidemic form, tonsillectomies be postponed until after the outbreak, unless there is some urgent indication for the tonsillectomy.

Care of Paralyzed Patients

As to the aspect of control where governmental agencies can be of greatest assistance—namely, care of the occasional person who develops the paralytic form of the disease—New York State is particularly well equipped to give such assistance after the febrile stage through the provisions of the Handicapped Children's Act for those under 21 years of age, and the Shaw Act for older individuals. In addition, a corps of specially trained orthopedic nurses and physiotherapists are on the staff of the State Department of Health, and in times of epidemic are shifted from their usual districts to the areas particularly affected. The department also provides diagnostic assistance through the medical staffs of its district offices, and consultation service by orthopedic surgeons. In the acute febrile stage, care is provided by the local welfare authorities for persons on relief, and by the local chapters and central office of the National Foundation for Infantile Paralysis in borderline cases. The assistance through this Foundation has been invaluable in the current outbreak.

Future Control

As to the possibility of better control measures in the future, it may yet be possible to devise effective specific therapeutic measures, although there is nothing very encouraging along that line at present; and treatment, at best, is less desirable than prevention. As to prevention, I see no possibility of preventing infection unless an effective, thoroughly safe vaccine is developed. This phase, of course, has not been neglected, and as soon as monkeys were first shown to be susceptible to poliomyelitis infection, attempts were made to prepare an effective vaccine. Unfortunately, the methods employed at that time to kill the virus in the preparation of an inactivated vaccine destroyed the antigenicity as well. Vaccines in which the virus continued to remain alive were effective in producing immunity, but they also resulted in producing the disease in a certain percentage of instances, so that the vaccine was actually more dangerous than the disease itself. This same cycle was again traversed about 1935, and the same conclusions reached.

As to recent attempts, Milzer, Oppenheimer, and Levinson[24] claim the production of a completely inactivated poliomyelitis vaccine found effective in protecting mice against the homologous mouse-adapted Lansing strain of the virus.

This vaccine was produced by the newly developed method of ultraviolet light irradiation for a fraction of a second. This is the first instance in which a completely inactivated poliomyelitis vaccine has been demonstrated to have retained its antigenicity. This experiment deals essentially only with mice and only with the Lansing strain, so one must not become enthusiastic as yet. Before any possible application to human beings, it must be tried on many more mice and in many monkeys, and with other strains of poliomyelitis virus besides the Lansing strain. Since this vaccine consists of mouse-brain material, the question also arises as to the possibility of sensitization reactions upon repeated injections of the material. Obviously, any vaccine used to prevent poliomyelitis must be an unusually safe product, since, even in epidemic times, only a very small percentage of the children are attacked with the serious form of the disease, and an unsafe vaccine may do more harm than good. However, this work by the Chicago workers is definitely encouraging, and it is barely possible that in a few more years the problem of poliomyelitis may be solved through active immunization.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY ANNOUNCES CHANGES IN REGULATIONS AND REQUIREMENTS

A number of changes in Board regulations and requirements were put into effect at the Board's last annual meeting. These were designed to aid civilians as well as candidates in the Service. Among these is the waiver, temporarily, of the A.M.A. requirement for men in the Army or Navy, especially for those who proceeded directly or almost so from hospital services into Army or Navy Service, upon a statement of intention to join promptly upon return to civilian practice. At this meeting the Board decided also to accept a period of nine months as an academic year in satisfying our requirement for certain years of training. This is only for the duration and even men who are not eligible for military service but who are nevertheless in hospitals where the accelerated program is in effect have been allowed to submit to us this short-time period of training in lieu of our previous requirements.

Beginning with the next written examination, which is scheduled to be held February 3, 1945, this Board will limit the written examination to a maximum period of three hours and in submitting case records at this time, all obstetric reports which do not include measurements either by calipers and, as indicated, by acceptable x-ray pelvimetry, will be considered incomplete.

Prospective applicants or candidates in military service are urged to obtain from the Office of the Secretary a copy of the "Record of Professional Assignments for Prospective Applicants for Certification by Specialty Boards" which will be supplied upon request. This record was compiled by the Advisory Board for Medical Specialties and is approved by the Offices of the Surgeons General, having been recommended to the Services in a circular letter, No. 76, from the War Department Army Service Forces, and referred to as the Medical Officer's Service Record. These will enable prospective applicants and candidates to keep an accurate record of work done while in military service and should be submitted with the candidate's application, so that the Credentials Committee may have this information in reviewing the application.

Applications and a bulletin of detailed information regarding the Board requirements will be sent upon request to the Secretary's Office, 1015 Highland Building, Pittsburgh 6, Pennsylvania.

The time and place of the Spring, 1945 (Part II) examination will be announced later.

COMMUNITY ORGANIZATION FOR THE CONTROL OF RHEUMATIC FEVER

DONALD B. ARMSTRONG, M.D., Sc.D , and GEORGE M WHEATLEY, M.D., M.P.H., New York City

THE purpose of this paper is twofold: (1) to suggest a plan for community action in the control of rheumatic fever; (2) to urge physicians interested in this disease to help initiate such community organization. Today, largely through the work of Swift,[1] Hedley,[2] Paul,[3] and others, physicians generally are aware of the public health importance of this disease in the United States. Along with tuberculosis and syphilis, rheumatic fever is now one of the "big three" remaining infectious disease problems in American communities.

Magnitude of the Problem

The public health importance of rheumatic fever is based not only on the contribution it now makes to mortality and morbidity, including its relation to cardiac pathology, but on the complex problem of providing adequate care for many of its victims. In spite of incomplete reporting of deaths due to rheumatic fever, the death rates for chronic rheumatic heart disease and acute rheumatic fever are not negligible. For example, in 1942 among the general population, the combined rate for all ages was 20 per 100,000.[4] In ages 5 to 19, it is, among diseases, the leading cause of death. And rheumatic fever mortality rates do not tell the whole story. The infection is responsible for a large fraction of cardiac deaths and for heart disease which completely incapacitates or hampers the economic productivity of thousands in their prime years. Clues to the size of this group are obtained by school medical surveys and the medical examination of draftees. Table 1 reflects the geographic incidence of rheumatic heart disease among school children in some major cities of the United States. In draft examinations in New York City in 1940–1941, heart disease was a cause of rejection in over 40 per 1,000 selectees.[5] And now, judging by the current reports on the occurrence of rheumatic fever among men actually in service, many more young individuals are included among its victims.[6] Clearly these facts call for organized efforts to control the disease.

Known Causative Factors

Our knowledge about rheumatic fever suggests certain points of attack. Like tuberculosis, socioeconomic factors appear to influence the occurrence of rheumatic fever. Epidemiologic studies show a high correlation between recurrence of rheumatic fever and such factors as crowded, unhygienic living conditions and poor nutrition.[14] The disease also tends to be concentrated in certain families[15] and may be influenced by psychologic factors as well.[16] Perhaps the most important of the causative factors is the role of the streptococcus in precipitating attacks of rheumatic fever. And now the promising use of sulfonamides to prevent recurrences is giving new impetus to preventive efforts.[17] These facts can be utilized in an organized fight to control rheumatic fever.

Organized Effort Necessary

Applying this knowledge, however, requires the proper mobilization and organization of community resources. Rheumatic fever, like tuberculosis, cannot be successfully attacked by the medical profession alone or from one angle alone. Furthermore, the difficulty frequently associated with the diagnosis of the disease suggests that expert diagnostic service be made available to the practicing physician to assist him and to encourage reporting of the disease. The tendency of the disease to recur demands that plans be developed to educate parents, teachers, social workers, and others in daily association with the child not only in good child-health care, including periodic medical supervision, but to recognize the manifestations of rheumatic activity. The prolonged and expensive care usually necessary during the active and convalescent stages of rheumatic fever implies that such care is often a community responsibility. The crippling effect of rheumatic heart disease suggests the impor-

TABLE 1.—OBSERVED AND ESTIMATED INCIDENCE OF RHEUMATIC HEART DISEASE IN SCHOOL CHILDREN IN THE UNITED STATES

Second Vice-President and Assistant Medical Director, respectively, of the Metropolitan Life Insurance Company.

tance of occupational guidance in certain cases. To meet these complicated needs, organized medicosocial effort is necessary.

Present Status of Organized Action

A start has already been made. In one state[18] and a few of the major cities,[19–21] heart associations have initiated rheumatic fever educational campaigns. There is a growing list of states and cities where the disease is reportable* and where case-finding surveys have been started. Some tuberculosis preventoria for children are being converted to the care of rheumatic fever victims.[22] In a few communities, cardiac consultation service for school children has been instituted.[23,24] Through special home-visiting service, several community visiting-nurse associations are aiding in preserving continuity of medical care.[25,26] These activities are promising signs of local action. All are part of a total community rheumatic-fever program. On the Federal level, the Children's Bureau, since 1939, has been assisting state agencies to develop services for children with heart disease.[27] In January, 1944, the American Heart Association began to unite the many national professional groups interested in rheumatic fever by sponsoring a conference in New York City. This was attended by some thirty delegates representing the various medical, governmental, and social organizations. At this meeting the following resolutions were adopted unanimously:

1. Because of the magnitude and importance of the rheumatic-fever problem, this conference is strongly in favor of the extension of public programs, supported by Federal, state, and local funds, for the study, prevention, and treatment of this disease. Moreover, we believe it essential that additional funds be secured from private sources for the purpose of special studies to increase basic knowledge of the disease, for professional education and for increasing public awareness of the problem.
2. In order to accomplish the purposes mentioned above, this conference recommends that a Council on Rheumatic Fever be formed under the leadership of the American Heart Association, and that this council shall include representatives of interested organizations.

Following this conference, the Board of Directors of the American Heart Association met in February, 1944, and proceeded to form a Council on Rheumatic Fever. The American Public Health Association, American Medical Association, American College of Physicians, American Academy of Pediatrics, American Rheumatism Association, National Organization for Public Health Nursing, American Nurses Association, American Hospital Association, and American Association of Medical Social Workers have named their delegates to this Council, which held its first official meeting in December, 1944.[28] But the expansion of public programs of care depends in large part upon a community's consciousness of the magnitude of its rheumatic-fever problem and its willingness and ability to shoulder its share of financial responsibility. The greatest need at the moment is a pattern for action to assist physicians and others conscious of the importance of rheumatic fever in the development of an over-all community program.

What Should Be the Points of Attack?

In searching for a guide, the similarity of many features of rheumatic fever to tuberculosis suggests that a study of the organized efforts to control tuberculosis might be profitable. One program which showed how a community could control its tuberculosis problem was the Framingham Tuberculosis Demonstration.[29] Not only was this the first comprehensive community effort to eradicate tuberculosis, but now for more than twenty years its lessons have been successfully applied over and over again in other communities. With rheumatic fever in mind, let us look at the chief features of the Framingham activity:

1. *The Magnitude of the Problem.*—It gave, for the first time, a fairly complete picture of the amount of tuberculosis actually existing in a typically American community. This is certainly the first step needed in a community program looking to the control of rheumatic fever. Before embarking on investigations to uncover the size of the rheumatic-fever problem, Dublin's[30] critical analysis of present methods of determining prevalence and incidence should be studied.
2. *Consultation Service.*—It has been said about the Framingham Demonstration that the most important of all practical contributions it made was to develop a plan for medical consultation service. Surely the difficulties associated with the recognition of rheumatic fever and frequently of rheumatic heart disease suggest that one of the great needs in this field is an expert consulting service for the practicing physician.
3. *Treatment.*—The value of adequate treatment of tuberculosis was demonstrated in Framingham. It is also necessary to demonstrate fully the importance of bed rest in the treatment of rheumatic fever and the advantages and disadvantages associated with

* The disease is now reportable in Michigan, Iowa, California, Rhode Island, Utah, Maryland, the District of Columbia, and Cincinnati, Ohio, and Chicago, Illinois.

institutional care, foster home care, and management of cases in the home

4 *Standards of Diagnosis*—As the Demonstration developed and emphasized the importance of diagnostic standards for tuberculosis, so are needed standards for the diagnosis of rheumatic fever The standardization and diagnosis of heart disease have been put on a very satisfactory basis through the efforts of the New York Heart Association and the American Heart Association But there are also needed comparable criteria which will assist the practicing physician in recognizing cases of rheumatic fever

5 *Death Certificate Analysis*—A careful analysis of death certificates for prior years by the Framingham group showed that the actual deaths from tuberculosis were 22 per cent in excess of the reported deaths from this disease As Hedley [31] has shown, analysis of vital statistics reveals that there is under reporting of deaths from rheumatic fever and rheumatic heart disease

6 *Environmental Studies*—The Demonstration emphasized the importance of the general environment as a contributor to the incidence and spread of tuberculosis It is clear from what we know about the development and spread of rheumatic fever that important environmental studies could be made as a part of any intensive study of rheumatic fever in a large community This would involve a study of the influence of housing, crowding feeding, etc , not only in homes, but schools factories, and other places where people are concentrated

7 *Health Education Activities*—These were a prominent part of the community Demonstration The work was channeled in two fields (a) measures of personal hygiene directed at the limitation of infection (b) measures which tended to promote an increased resistance to disease and which encouraged hygienic living These same principles, even with our lack of complete knowledge with respect to a causative agent in rheumatic fever and the exact mode of transmission, can be used in educating the public about the disease

The fact that tuberculosis was a reportable disease at the time of the Framingham Demonstration perhaps helped in initiating control measures Certainly reporting and registering of rheumatic fever cases are two prime objectives in a community program But reporting is not a necessary condition for initiating a community effort Community education, consultation service, development of standards of diagnosis, efforts at environmental improvement, provision of adequate facilities for treatment are all essential in a well conceived community plan Nevertheless, depending upon local circumstances, any one approach might be undertaken as the initial effort

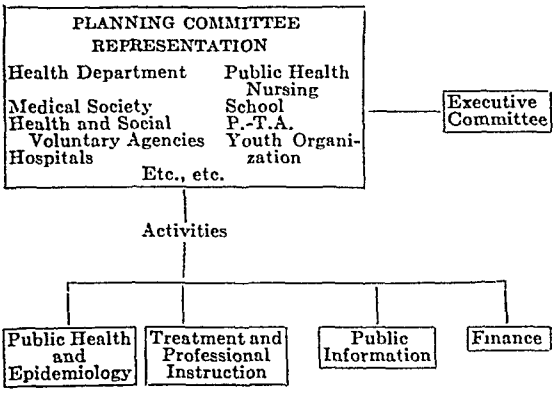
How Are These Objectives to Be Attained?

For a long-range program, such as this must be, the initiative should come from within the community Information and technical assistance may be supplied from outside to inform and interest community leaders, but in order for the program to be accepted and supported by the community, it must be initiated and carried out by members of the community. A community rheumatic fever program involves the cooperation of many groups and individuals The physician is the ideal person to call attention to this disease and secure the help of key people in the community To illustrate what medical leadership can accomplish, we offer the description of one who has been an eye witness in the development of the community rheumatic fever program in Stamford, Connecticut [32]

"We have much to be thankful for—chiefly in the caliber of the people who planned the organization—the doctor, the president, and the executive board They were convinced of the need and set out to conquer all obstacles

"It seems that a few key people must be ready before the plan will 'take'—the vitalizing energy must come from within and the doctor is the person from whom the original plans must come Our growth which has come about by luck, good management, and mistakes, was as follows

"There was



1 A physician to shape the program who was quiet, determined, and unafraid
2 A practical, wise, and vitally interested president of the Cardiac Aid, able and willing to cope with difficult situations, as they arose
3 An intensive educational program—by placing on the Cardiac Aid key people from every organization in Stamford
4 An assignment of special active duties to certain organization representatives, such as the Visiting Nurse Association and the Parent-Teachers' Association, thereby bringing information regarding heart disease to the parents from every possible source
5 A plan with the Board of Education and the school nurses so that all cases found in the school examination program could be registered with the Cardiac Aid and a home teacher provided by the School Board for home-bound children
6 An agreement with the State Crippled Children's Division for the registration of all cases having a positive diagnosis They have helped with the expense of some of the children at camp
7 An affiliation with the local Lion's Club for financial aid and advice The group in Stamford is represented by keen, enthusiastic,

and energetic businessmen with big hearts and sound heads.

8. An introduction of a bill into the State Legislature this year to make rheumatic heart disease reportable.
9. A gradual drawing-in of key people from surrounding towns to serve with the Cardiac Aid so that our field of usefulness would be widened.
10. A need for convalescent care which was not met until 'Camp Lionheart' was born. For the duration this must suffice—six weeks' care to each of thirty-six children."

In localities where a Council of Health Agencies exists or where there is any one major health agency, perhaps a tuberculosis association, such an organization may offer the machinery for initiating a community interest in the rheumatic-fever program. Certainly in directing lay and professional attention to this problem, no community agency has a greater opportunity or obligation than the local medical society. Where there is no community group in existence which might locally serve as the framework for organization, the initiative may be taken by the interested physician with the assistance of the health officer and lay community leaders. They could organize a planning committee such as is illustrated by Chart I.

CHART 1.—Suggested Committee Organization Chart

The health department representative would be the health officer or his delegate; the representatives of the medical society would probably and desirably be pediatricians and heart specialists, as well as general practitioners. There should be representatives from organizations doing family case work as well as from the department of public welfare. It would be desirable also to have nursing, education, civic, religious, business, and labor interests represented on the committee. An executive committee would probably be necessary to act for the overall planning committee in the interim periods between meetings, composed perhaps of the chairmen of the subcommittees. A general function of this committee would be to study the extent of the local problem and to report back to the agencies represented upon it. A complete committee program might be carried out through four subcommittees as shown on the chart: one on public health and epidemiology; one on treatment and professional instruction; one on public information; and a finance committee, the latter's functions being to estimate financial needs and find ways to meet these needs without developing a separate fund.

What would be the scope of such a planning committee? Space does not permit the development of all the possible activities of the committee. However, as an indication, for instance, of the "public information" activities, the objectives recently outlined by a committee of the New York Heart Association for a public-education program in New York City which began in October, 1943, in cooperation, of course, with medical and social efforts, are as follows:

1. To secure early medical care for children with signs indicating the actual or probable presence of rheumatic fever
2. To protect children who have had rheumatic fever, so far as possible, from the recurrence of attacks, and give care required for general health building
3. To develop a healthy attitude toward the handicapped child and aid him in developing a healthy attitude toward his handicap
4. To protect healthy children from infection, within the narrow limits of present-day knowledge.

This program is being carried out to a limited degree on a city-wide basis, and, at the same time, more intensively in one Health District.

Schools of medicine and of public health, of education, social work, and of nursing, are being reached in this educational effort as well as nurses, social workers, women's clubs, church groups, labor organizations, parents and teachers, and other lay groups.

The suggested organization chart and related plans may seem too ambitious for a small community. It may not have enough of a rheumatic-fever problem to justify an elaborate community organization. On the other hand, an active informed group, even in a small community, can interest the proper agencies and individuals in neighboring communities. Such action may result in several communities cooperating to form a larger operating unit. The plan might be developed, therefore, on a county or health-district basis.

Although the problems incompletely discussed are many and complex, this should not discourage community action. Begin with one phase of the problem. Again, this will depend

upon local circumstances. If a cardiac clinic for children already exists it may be the starting point.

The group interested in this can serve as a nucleus to arouse other community groups who can be brought together to serve on a planning committee. Another approach may be through the schools. A carefully conducted survey of school children to determine the incidence of rheumatic heart disease may be the means of arousing interest in a more extensive attack on the disease.

The Physician Holds the Key to Control

If the magnitude of the rheumatic-fever problem is to be disclosed and brought home to the various localities throughout the country; if there is to be intelligent action on the basis of what is known about the problem in the community; and most important, if there is to be sustained public support of the efforts to control this disease, community organization, we believe, needs to be undertaken. In this program of community action, the physician and his medical society can and must play a leading part.

Yesterday, the physician treating sick people was a lone worker. Recovery of the individual patient often hinged entirely upon the physician's own therapeutic resourcefulness. Today, in the management of such complex diseases as syphilis, tuberculosis, and rheumatic fever certain new and technical phases of diagnosis and therapy are apt to be auxiliary to the routine experience and facilities of the general practitioner. Expert laboratory and consultative aid and cooperative group professional arrangements may be more frequently necessary. Today, also, the physician depends upon many other nonmedical individuals and agencies to enable him to bring to his patient the complete galaxy of modern medical resources. And yet, as the focal point for these facilities and services, he today more than ever holds the place of leader in community organization for the control and prevention of disease.

RED CROSS WAR FUND DRIVE STARTS MARCH 1

Area chairmen for the 1945 drive of the Red Cross War Fund in New York City were announced on January 1 by Walter L. Barber, fund chairman. The campaign will begin on March 1.

Jarvis Cromwell will be borough chairman for Manhattan. Last year he headed the special gifts committee. Mr. Cromwell will be the only borough chairman serving as such for the first time.

Mr. Barber will continue as Brooklyn chairman. The Bronx drive will be led by Raymond L. Korndorfer.

Ambrose B. Acker, president of the Chamber of Commerce of the Borough of Queens, will share the [illegible] chairmanship in Central Queens with Mrs. [illegible]

The Staten Island drive will be conducted under the cochairmanship of Ernest Miller and Mrs. Alfred Shriver, Red Cross liaison representative at Halloran General Hospital.

THE MANAGEMENT OF THE PATIENT WITH PROSTATIC URINARY OBSTRUCTION

CLARENCE G. BANDLER, M.D., F.A.C.S., and PHILIP R. ROEN, M.D., New York City

THE increasing span of life of the average individual has brought into greater prominence the treatment of the older patient with diseases peculiar to his time of life. Physicians speak more and more of geriatrics, and the patients themselves, because of various newspaper and lay-magazine features, have given more attention to their ailments and have come to the physician earlier in the course of these ailments. One problem in particular, that of the "prostate," has been the subject of recent popularization. It is for these several reasons that the urologist has had not only an increasing number of patients with urinary prostatic obstruction come under his care, but it is found that these patients are "better risk" patients—they have not permitted a long lapse of time between the onset of symptoms and the seeking of medical aid; for example, we find fewer patients with advanced renal damage from prolonged back-pressure.

Undoubtedly, this is a great factor in lowering the mortality rate for prostatic surgery, but much more credit must be given to the modern methods employed in the management of patients with enlarged prostate glands. It is the purpose of this presentation to review the steps in the management of such patients, as followed in our clinic, and to re-emphasize the value of a little-used simple technic in the preliminary drainage of the urinary bladder.

Preoperative Management

In selecting the title for this presentation, "The Management of the Patient with Prostatic Urinary Obstruction," we have been motivated by the fact that in all of surgery there is no other problem in which the entire patient must be considered more carefully rather than the specific surgical lesion. Hence, the problem involved is to be regarded not as one of a "prostate" but as that of a patient who incidentally happens to be afflicted with prostatic urinary obstruction. Because the patient with a prostatic lesion is in the more advanced decades of life, diseases such as arteriosclerosis, chronic cardiac condition, hypertension, diabetes, pulmonary states such as chronic bronchitis and empyema or asthma, must be completely recognized and treated, and their possible influence on the outcome of the operative procedure should be anticipated. The preoperative treatment of the obstructing prostate gland then resolves itself into two phases:

From the Department of Urology, New York Post-Graduate Medical School and Hospital, Columbia University.

1. Medical Preoperative Preparation.—Needless to say, a complete history and thorough physical examination are performed. In addition, laboratory tests, including a complete blood count, urinalysis, blood sugar, urea nitrogen, carbon dioxide combining power, and blood Wassermann determinations are routinely done. Evaluation of the cardiac status, including electrocardiographic study and consultation with a cardiologist (where indicated) is a necessary prerequisite for low mortality. Full cooperation of the internist is essential; when diabetes is found the patient is stabilized before surgical intervention is undertaken. Anemia is overcome by the liberal use of transfusions of whole blood or concentrated erythrocytes, depending upon individual needs.

Adequate blood-chemistry studies and renal function tests in the preoperative study of the prostatic patient have long been known and established. It is our practice, in addition to these, however, to perform excretory urography routinely on every patient. This gives more valuable information than any single study; calculi in the urinary tract or prostate may be seen; detection may be made of osteoarthritis or metastatic prostatic cancer or other conditions of the osseous system; the presence or absence of hydronephrosis or hydroureter is observed; bladder contour, cellules, diverticulae, and the size of the prostatic filling defect are determined. Not only do we secure an estimate of the functional capacity of the kidneys, but we can in general give a prognosis as to the surgical convalescence. Prompt renal function and delineation of a normal urinary tract generally presuppose an uneventful postoperative course, while delayed function with bilateral dilatation of the ureters and kidney pelvis indicates that prolonged preoperative preparation is required. Figs. 1 and 2 show the comparative status by x-ray of the upper urinary tract in a patient who was carefully prepared and operated upon successfully.

2. Urologic Preoperative Preparation.—While the patient is being studied in the fashion described above, attention is, of course, directed to the urinary problem, and we find that the cases can be divided into three distinct groups:

(*a*) Patients who require no preoperative catheterization except for the determination of residual urine. These patients are able to void, and, though presenting definite symptoms of

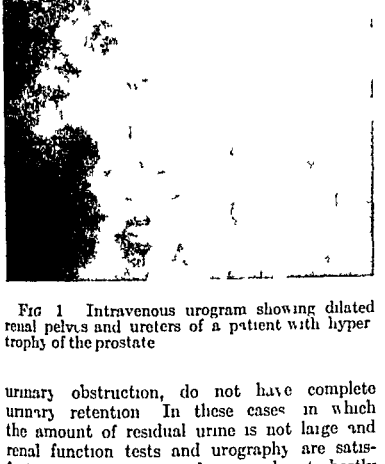

FIG 1 Intravenous urogram showing dilated renal pelves and ureters of a patient with hypertrophy of the prostate

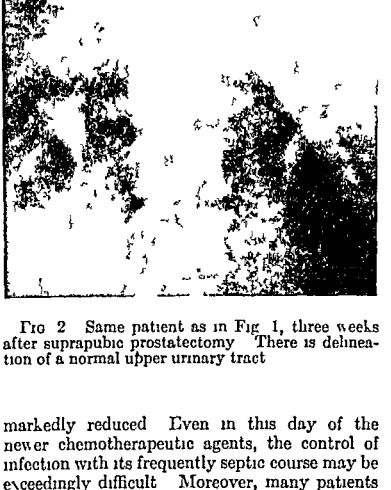

FIG 2 Same patient as in Fig 1, three weeks after suprapubic prostatectomy There is delineation of a normal upper urinary tract

urinary obstruction, do not have complete urinary retention In these cases in which the amount of residual urine is not large and renal function tests and urography are satisfactory, operation may be carried out shortly after admission to the hospital

(*b*) A second group comprises those with acute urinary retention of recent origin The preferred manner of treating such patients until the time of operation, is to employ periodic catheterization, say at eight-hour intervals When a patient arrives at the hospital, wearing an indwelling catheter which has been in place for some time, we permit such a catheter to remain *in situ* A word might be said here relative to catheterization a completely aseptic technic must be combined with extreme gentleness and the use of the proper catheters The rigid metal catheter, often in use by the physician in general practice, is mentioned, only to be condemned Where a soft rubber Coudé catheter does not pass easily, a silk woven Coudé catheter should be used with caution and with the admonition that no instrument should be introduced by force into the bladder for fear of producing a false passage in the urethra

(*c*) In the third group are those patients who have impairment of renal function, as demonstrated by elevation of the blood urea nitrogen, and the presence of an enlarged, chronically distended bladder In such cases a prolonged period of drainage is required, and these cases are ideally suited for the procedure of suprapubic trocar cystostomy The risk of infection (epididymitis, urethritis, cystitis, and pyelitis) resulting from the presence of an indwelling catheter is very great, and by eliminating such a possibility, the mortality in prostatic surgery can be markedly reduced Even in this day of the newer chemotherapeutic agents, the control of infection with its frequently septic course may be exceedingly difficult Moreover, many patients cannot tolerate an inlying catheter Open suprapubic cystostomy is definitely undesirable for routine use and we have, therefore, adopted another method which is eminently more satisfactory than the inlying catheter or open cystostomy This consists of suprapubic puncture of the bladder by trocar and cannula

We are deeply indebted to Dr William E Lower and two of his associates, Dr Charles C Higgins and Dr William Engel, of the Cleveland Clinic, who introduced us to this technic and taught its use The instrument employed (*v* 1) is Dr Lower's modification of his original model, and is as yet unobtainable commercially However, various types of trocars, such as are found in the usual surgical armamentarium, are applicable for suprapubic cystostomy

Suprapubic puncture of the bladder, employing a trocar and catheter, has been employed occasionally for many years, but its widespread use has been handicapped by the fear of penetrating the peritoneum or a loop of bowel No such complication has been seen in several thousand such procedures performed by Lower, Higgins, and Engel, nor have there been any mishaps in our experience (about 200 cases) There is no such danger, provided that there is adequate distention of the bladder and it is palpable above the symphysis pubis

This method of suprapubic drainage has been found especially advantageous when a long period of time is necessary for adequate prepara-

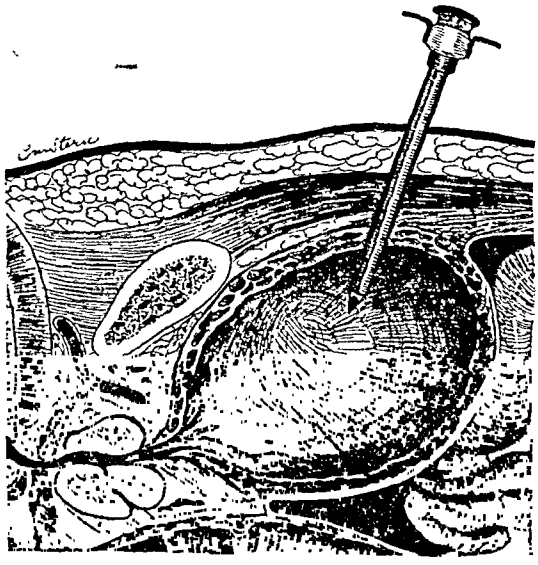

FIG. 3. Position of trocar and cannula in relation to pubis and peritoneum after the instrument has been plunged into the distended bladder.

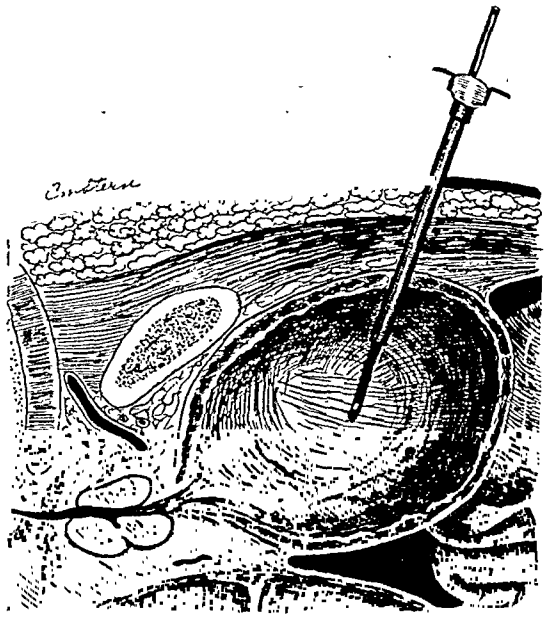

FIG. 4. After the trocar is removed, a catheter is threaded through the cannula into the bladder.

tion of the patient for operation. The catheter is easily cared for, unclamped whenever emptying of the bladder is required, and, moreover, there is no urinary leak about the catheter. It is also ideally suited for those cases in which permanent suprapubic bladder drainage is necessary and is a boon in the care of patients with paralysis of the bladder due to spinal cord disease or injury. This procedure should also be employed in the armed forces when spinal-cord injuries necessitate transportation for great distances before proper reparative surgical measures may be instituted.

On removal of the suprapubic catheter, almost miraculously, one sees the closing of the fistulous tract within three or four hours, and closure is rarely delayed longer than forty-eight hours even in those cases in which the catheter has been in place for a long time.

The virtues and advantages of this method cannot be too loudly extolled, and it deserves wider recognition and use.

The technic of the procedure is relatively simple (see Figs. 3, 4, 5). Local infiltration anesthesia or, if so desired, intravenous sodium pentothal is employed. The patient is placed in slight Trendelenburg position and the bladder is distended by an urethral catheter, if it is not already distinctly palpable. The suprapubic region is aseptically prepared. A long spinal needle is inserted at a point 2 to 3 cm. above the symphysis pubis, and advanced into the bladder. When the latter is entered, fluid escapes through the needle at once. A 1-cm. transverse incision is then made in the skin at this site, and the underlying deep fascia is incised longitudinally. The trocar and cannula are inserted through the skin incision and plunged into the bladder with a rotating motion. The trocar is removed and a No. 18 F. soft catheter is immediately passed into the bladder through the cannula, which is then removed. The catheter is fastened into place with a single silk suture passing through the skin and the catheter itself. Replacement of this catheter by a Foley self-retaining catheter may be made on the fourth or fifth day following suprapubic trocar puncture.

The instrument is also adapted for the use of a cystoscope (No. 18 F. McCarthy cystourethroscope, or the No. 18 F. McCarthy panendoscope), and visualization of the bladder may be carried out through the instrument at the time of trocar cystostomy or may be done subsequently when the fistulous tract is well established. Such a procedure is of inestimable aid when stricture of the urethra or intraurethral prostatic intrusion precludes cystoscopy through the urethra.

Routine urologic preoperative management of the patient also includes cystoscopic examination. The McCarthy panendoscope is employed regularly. This permits, primarily, the determination of size of intraurethral and intravesical enlargement so that the proper surgical method may be appropriately chosen. The exact type of prostatic enlargement, median bar, lateral lobe hypertrophy, or various types of lateral and median lobe hypertrophy, is revealed. Such complicating intravesical conditions as calculus, tumor, diverticulum, and

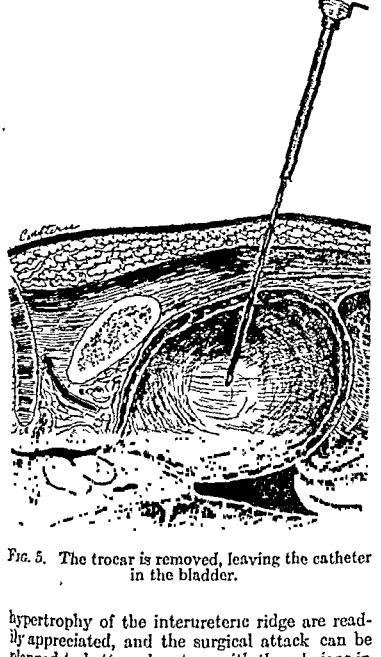

FIG. 5. The trocar is removed, leaving the catheter in the bladder.

hypertrophy of the interureteric ridge are readily appreciated, and the surgical attack can be planned to better advantage with these lesions in mind. We do not feel, as others have stated, that preoperative cystoscopy is unnecessary or undesirable because of the potential danger of infection. It is our opinion that every patient should have cystoscopic examination preoperatively, for when we ascertain exactly what problems are involved, we can better plan the surgical procedure.

The Operative Procedure

This procedure depends on the various factors discussed above, and particularly on the size of the obstructing gland. It is not our purpose here to enter into debate as to the relative merits of the three methods employed, namely, the transurethral, suprapubic, and perineal approaches. Suffice it to say that approximately 80 per cent of all of the prostatic surgery done at this clinic is performed transurethrally. As experience has increased, the safety of this operation and the completeness of the resection have also increased. This method also reduces the number of days of confinement to bed, thus further lowering the mortality rate. We shall probably see an increase in this type of surgery, for, as Kretschmer has written, "the older and feebler they are, the more justification there is for transurethral resection." With respect to open surgery when such is indicated by the size of the prostate gland or by complicating factors such as tumor or diverticulum, we prefer suprapubic prostatectomy.

Routine vasectomy is not practiced when either suprapubic or transurethral surgery is employed, for the incidence of epididymitis in our experience has been so low that such a procedure is not essential.

In those cases in which preliminary suprapubic trocar puncture has been employed, the suprapubic catheter, together with the urethral catheter, serves as a means of through-and-through constant bladder irrigation by the drip method following the procedure of transurethral prostatic resection. Where suprapubic prostatectomy is done, this preliminary drainage method does not obliterate tissue planes, as occurs with open suprapubic cystostomy, and this approach and suture of layers is as though one were performing one-stage prostatectomy.

Carcinoma of the prostate presents a special problem which must be considered separately. Total perineal prostatectomy undoubtedly is the surgical method of choice for carcinoma of the prostate when the prostate can be entirely removed. In most cases, however, when the patient is first seen by the urologist, complete surgical removal is a technical impossibility because of the invasion of the periprostatic tissues by the carcinomatous mass. In this event, when obstructive urinary symptoms and findings are present, transurethral resection and bilateral orchiectomy are indicated. When obstructive urinary symptoms and residual urine are absent, bilateral orchiectomy alone should be done.

Anesthetic agents used in these surgical procedures are very important, for the proper anesthetic reduces the operative risk, particularly in "poor risk" cases. Low-spinal anesthesia is the preferred agent for transurethral resection, though caudal anesthesia may be employed. Where suprapubic prostatectomy is done, cyclopropane, in our experience, has produced the least disturbance in the patient's status, especially where cardiac disability exists, but, of course, this inhalant gas must be given by a skilled, trained anesthetist. Pentothal sodium may also be used in selected cases for either transurethral or open prostatic surgery.

Postoperative Care

Postoperative care includes the restoration of blood lost at the operating table. Numerous recent studies have disclosed that even during

the resection of a small prostate gland, 250 to 500 cc. of blood are lost, and in the older age group this is a serious matter. Restoration by transfusion is employed almost routinely. Adequate fluid intake (3,000 cc. daily) is achieved by giving parenteral fluids when necessary. The early use of the sulfonamides and penicillin in those cases in which the infecting organism is susceptible to the latter drug enables us to more readily control the sepsis which was the bane of the older urologic surgeon, and aids in decreasing the mortality rate. We must also emphasize the early removal of the indwelling catheter, for this factor alone, as previously discussed, is often instrumental in the onset of urinary infection.

It is, moreover, our practice to permit our patients to be out of bed at the earliest possible moment consistent with the surgical procedure. Such a measure is especially necessary in the older age group, in which prolonged bed rest may lead to hypostatic pulmonary congestion and pneumonia, or phlebitis and embolism.

In conclusion, we can readily state that there is a distinctly better outlook for the patient with an obstructing prostate gland who requires surgery, and he can rest assured that with individualization of his problem, with excellent preoperative attention to *all* of his physical disabilities, and with careful choice of the surgical procedure to be followed, his chances of surviving the operation are excellent.

Summary

1. The treatment of the patient with prostatic urinary obstruction is delineated.

2. Complete preoperative preparation demands not only attention to the urinary obstruction but complete evaluation of the entire patient, including his cardiac, pulmonary, and renal status.

3. Description of a method for suprapubic trocar cystotomy is given, its importance is stressed, and a plea is made for its wider use.

4. The methods of surgical attack and postoperative care are briefly discussed in relation to the task of minimizing the operative mortality.

DIRECTOR ASKS DOCTORS' AID FOR SOCIAL HYGIENE DAY

Dear Doctor:

Once again I write to invite your cooperation in the ninth annual celebration of Social Hygiene Day on February 7, 1945. The enclosed leaflet explains the general aims of this year's meetings. As physicians we have a special responsibility for the protection of health and the prevention of venereal diseases. It is chiefly by constant vigilance and by finding and treating the sources of infection that we can contribute to lowering rates, while expanding programs on the moral, social, and educational sectors are providing effective preventive measures.

The medical and public-health procedures which, if faithfully applied, will check any increase in these infections and reduce their prevalence are known to us. But unless the public knows enough to seek a physician's advice and care when the possibility of infection exists, there is little that we can do even with our present improved methods of diagnosis and treatment. Instruction of the public, therefore, is a most essential procedure.

I hope that you and your society will be able to help in this educational undertaking in the following ways:

1. By giving suitable publicity to Social Hygiene Day so that members of your society may know about it.

2. By accepting invitations to address lay audiences or to give radio talks on subjects relating to syphilis and gonorrhea.

3. By counseling with leaders of lay organizations who may seek your advice and aid.

4. By joining in the sponsorship of local or regional Social Hygiene Day meetings.

5. By calling the attention of your Woman's Auxiliary to the opportunity for service connected with Social Hygiene Day.

If, in connection with any of the above suggested activities, the American Social Hygiene Association can be of assistance, I hope that you will write to us.

Yours sincerely,
CHARLES WALTER CLARKE, M.D.,
Executive Director

COURSES OPEN AT MT. SINAI HOSPITAL

Mount Sinai Hospital in affiliation with Columbia University will offer a supplementary course in gastroenterology and another in bedside clinics in diseases of the liver and gallbladder, the classes to be held at Mt. Sinai on Wednesdays from February 7 to March 28. Inquiries and applications should be addressed to the Secretary of Medical Instruction at the Hospital.

THE ELECTROFIT IN DEPRESSION—COMPARISON OF HOSPITAL AND PRIVATELY TREATED PATIENTS

DAVID J. IMPASTATO, M.D., JOHN FROSCH, M.D., RENATO J. ALMANSI, M.D., and S. BERNARD WORTIS, M.D., New York City

THIS work was undertaken to study (1) The effect of the electrofit on ambulatory patients treated in private practice and a group of patients treated while in residence in the Psychiatric Division of Bellevue Hospital; (2) the effect of sodium amytal on the electrofit; and (3) the effect of a high or increasing convulsive threshold on the therapeutic outcome.

Material and Procedures

Patients.—Group A (Table 1) was treated in Bellevue Hospital. These patients received 0.3 Gm. sodium amytal intravenously from two to fifteen minutes prior to the electrofit. Most of these patients received treatment two to three times weekly, while a small number received treatment six times a week. All had pre- and posttreatment x-rays of the thoracic spine. Group B (Table 2) was treated at Columbus Hospital as ambulatory patients. These subjects were given sodium amytal only if they became much disturbed after the first convulsion. Most of them received treatment twice weekly. A few were treated three or four times weekly. They had x-ray of the thoracic spine only if they complained of high-back pain.

Treatments were usually given to both groups in the morning before breakfast. The patients' backs were hyperextended on the lower half of the Gatch bed, and during the convulsion were held firmly by three or four attendants. We attempted to give the patient a grand mal convulsion at each treatment. To achieve this, multiple electric stimulation was given when necessary.

Sixty-three patients of each group suffering with depression are compared for therapeutic results.

One hundred and ten cases of each group suffering from various psychoses are compared for fracture incidence.

Results

Comparison of the Effect of the Electrofit on Private Patients Receiving Ambulatory Treatment, and on Hospital Patients Receiving Treatment While in Residence at Bellevue Hospital.—Summary of our results in the private ambulatory group shows that 45 of 63 patients recovered or were much improved, 16 were improved, and 2 were unimproved shortly after (within one month) treatment—immediate results.

Follow-up or late results of this group (two to forty months after treatment) showed: recovered or much improved, 47; improved, 7; and unimproved, 9. Some patients shifted from one group to another during the follow-up period. Of the original 45 patients who recovered or were much improved immediately following the treatment, 4 became moderately worse and shifted to the improved group, and 3 relapsed and shifted to the unimproved group. Of the original 16 patients who improved 9 became better and shifted to the recovered and much improved group, and 4 relapsed and shifted to the unimproved group. The greatest shifts occurred in the improved group.

In the Bellevue-treated patients the immediate results were: recovered or much improved, 41; improved, 17; unimproved, 5. These results are not quite as good as the immediate results in the private group. Of the Bellevue group we have follow-up findings on 24 patients. Of these 24 patients there were originally 18 recovered or much improved, and 6 improved. After a two- to ten-month period there were 13 recovered or much improved; 4 improved; and 7 unimproved. These results are definitely poorer than we obtained in the ambulatory group.

It appears that the private ambulatory patient responds better to the electrofit than the clinic patient. The following may be pertinent factors for this finding:

(*a*) The relatively better economic stability of the patient.

(*b*) The continued solicitation, interest, and care by the relatives.

(*c*) The possible better physician-patient relationship based on freedom of choice by patient.

(*d*) Since the ambulatory patient gets well while at home, there is no need for subsequent home readjustment. Such readjustment must be achieved by the hospital patient at the end of the treatment.

(*e*) The ambulatory patients might be considered as suffering from milder forms of depression, as they do not include those who are severely depressed, resistive, or actively suicidal.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 9, 1944.

From the Psychiatric Department of Bellevue Hospital and the New York University Medical College, and the Neuropsychiatric Service of Columbus Hospital.

The Use of Sodium Amytal Intravenously as an Adjunct to Electrofit Therapy

Intravenous sodium amytal, 0.3 Gm., and occasionally 0.5 Gm., was given from two to fifteen minutes prior to the electrofit to all of the Bellevue patients. The purpose of the administration of this drug is to:

1. Reduce the fracture rate, especially of the thoracic region. We have given sodium amytal intravenously to 110 patients at Bellevue Hospital. These were carefully checked with x-rays of the thoracic spine before treatments were begun, and again at the end of the treatments. None of these patients sustained fractures. Out of the last 110 privately treated patients who did not receive sodium amytal, 3 sustained fractures of the thoracic vertebrae. Inasmuch as we x-rayed only those who complained of high-back pain, the fracture rate may possibly be a little higher than the 3 reported. We realized that the group of 110 amytal-treated patients with no fractures is too small to draw definite conclusions from.

2. Reduce the apprehension of the patient prior to treatment. Fear of the treatment in electrofit therapy exists in a mild degree in about 50 per cent of the cases. It is nowhere as great as the fear expressed in metrazol convulsive therapy. Fear in electrofit therapy is not caused by any unpleasant experience felt during the treatment, for the patient has no memory whatsoever of treatment, but to the unpleasant thought of becoming unconscious.

There is a small group of patients, mostly extremely agitated and depressed, who resist any attempt to help them in any way whatsoever. They naturally also resist electrofit therapy.

In both of these groups the fear or resistiveness is immediately overcome by intravenous sodium amytal and they then submit to treatment without any difficulty.

3. Prevent the postconvulsive motor restlessness. Following electrofit therapy from 20 to 30 per cent of the patients show motor restlessness varying in intensity from tossing about in bed to furor reactions, during which they are extremely assaultive and destructive. These reactions occur after the convulsion while the patient is in the twilight state, just before regaining full awareness. During this abnormal behavior, which usually lasts from one to two minutes, the patient, personnel, and property may be injured. Later the patient has no recollection of his behavior.

Once the patient has exhibited postconvulsive abnormal behavior he will most likely show it on subsequent treatments.

The patient who has received sodium amytal does not regain consciousness after the convulsion, but goes into a sleep lasting from ten minutes to hours, and upon awakening behaves in a normal manner.

4. Reduce the blood pressure, thus making it possible to treat hypertensives with no added risk.

Sodium amytal temporarily lowers the blood pressure from 10 to 20 mm. in normal individuals and up to over 100 mm. in advanced hypertensives. We have found that the blood pressure rises from 0 to 50 mm. of mercury after a convulsion. This rise usually begins a half minute after the end of the clonic phase, reaches its maximum in one and one-half to two minutes, and returns to normal in three to five minutes. In hypertensives given sodium amytal the post-treatment blood pressure hardly ever surpasses the preamytal blood pressure. Table 3 gives a few readings of pre- and post-convulsive blood pressures, with and without sodium amytal.

5. In addition to the advantages outlined above, the administration of sodium amytal is time-saving for the shock-team personnel, especially when a large number of patients are to be treated over a given time, as the patient falls

asleep immediately after the treatment and other patients can be brought in and treated.

Effect of a High or Increasing Convulsive Threshold on the Curative Process

It has been said by some workers that an initially high convulsive threshold or an increasingly higher threshold as the treatment progresses is a good prognostic sign. We have not found this to be the case with our material. Regarding convulsive thresholds it may be stated that in general they are low in young patients and increase with age, being highest in elderly women. There are many exceptions to this general trend. These findings, however, bear no relation to the prognosis of the patient's illness.

Conclusions

1. Privately treated ambulatory patients seem to respond better to electrofit therapy than do clinic patients treated in hospital residence. The reason for this has not been established A number of possible pertinent factors are mentioned.

2. In 110 patients who received intravenous sodium amytal prior to the electrofit, none sustained a fracture of the vertebrae.

3. We have not found an initially high or a progressively increasing convulsive threshold a good prognostic sign. In our opinion this bears no relation to the therapeutic result.

4. We strongly recommend sodium amytal as an adjunct in electrofit therapy.

Competition for Prize Essays

The Merrit H. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York.

The Lucien Howe Prize of $100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merrit H. Cash Prize of $100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed:

Essays shall be typewritten or printed with the name of the prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing *the name and address of the writer.*

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded.

Any essay that may win a prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than February 1, 1945, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York 17, New York.

CHAS. GORDON HEYD, M.D., *Chairman*
Committee on Prize Essays

SURGICAL TREATMENT FOR DYSFUNCTION OF THE TEMPOROMANDIBULAR JOINT

ROBERT THORNTON PERCIVAL, Maj., (MC), USA, Brooklyn

THIS is a report of the surgical treatment of six cases of dysfunction in the temporomandibular joint with pain and snapping. All these patients had had the usual forms of therapy, such as removal of teeth to adjust the occlusion, injections into the joint, diathermy, chin bandages, chiropractic manipulations, etc., but with no relief. In these cases two forms of pathology were noted which should be differentiated, as the treatment depends upon this.

First there is the true recurrent subluxation of the joint, which is due to a shallow condylar fossa which allows the condyle to ride forward over the articular tubercle. It is then pulled back into position by the action of the muscles. This is an unstable joint, as is seen in the shallow acetabulum of congenital hip dislocations, and is shown by planogram (see Fig. 1).

The second type is due to an internal derangement of the interarticular fibrocartilage in which the fossa is deep enough. In this type there is usually a detachment of the cartilage from the capsule of the joint, allowing it to slip forward with motions of the jaw, and then snapping back with a loud click. The capsule is relaxed in all cases (see Fig. 2).

None of these cases had a history of jaw dislocations needing reductions and all developed over a period of years, gradually becoming more pronounced.

The patient complains of snapping in the jaw when he opens his mouth and pain referred to the temporal region. Some complain of pain in the ear. The noise is very embarrassing to women and some patients say their sleep is interfered with because the jaw snaps when they are about to fall asleep and wakes them.

Local anesthesia is used with adrenalin. This is very important, as the area is very vascular and oozing interferes considerably if a general anesthetic is used. Also, the patient moves his jaw, which is a great aid in finding the joint and in excising the cartilage. Moreover, there is no postoperative vomiting which might undo the correction obtained at operation.

The incision for operation is a straight one just in front of the ear extending from 1/2 inch below the external meatus straight upwards for 4 inches, which allows room for wide retraction and exposure of the temporal fascia. The scar is then in a natural fold of skin or in the hairline, and leaves no visible marks (see Fig. 3).

The auriculotemporal nerve and superficial temporal vessels are retracted backwards. The zygomatic fascia is incised along the zygoma and the upper part of the parotid with the facial nerve retracted downwards, exposing the joint. The capsule is incised and the interfibrocartilage is explored and removed by detaching from the joint capsule. There is usually some bleeding at this joint, so the joint should be packed.

A strip of the temporal fascia about 2 inches by 1/4 of an inch is next turned down and the lower end anchored as shown in Fig. 3. The upper end is attached to the periosteum below the articular surface of the condyle by silk sutures to reinforce the capsule.

The temporal fascial defect is closed by chromic suture and fine stainless steel wire is used to close the skin. A small rubber-band drain is left down in the wound for twenty-four hours and then removed.

In cases with a true recurrent subluxating joint, a type of shelf operation is used which deepens the fossa and prevents the condyle from riding over the articular tubercle. The same incision is used, but the incision is retracted more widely to allow the zygomatic fascia to be split further forward, exposing the zygoma for one inch in front of the joint. A small osteotome is inserted in the zygoma in front of the fossa and a shelf is turned downwards and backwards as in the shelf operation for congenital hip dislocation. It is held in place with a small wedge of bone from the under side of the zygoma, forming a shelf to prevent the condyle riding forward. The wound is then closed as before, with drainage;

Fig. 1

Fig 2A

Fig. 2B

also the temporal fascia is brought down as before to reinforce the capsule.

There has been no recurrence of symptoms in any of these cases. There is usually a transient paralysis of the side of the forehead affected, full function of which returns in about three weeks.

A many-tailed bandage was used to hold the jaw closed in the first cases, but this has been discarded as the patient keeps the jaw closed himself and the bandage is very uncomfortable.

Patients are kept on fluids given through a drinking tube for about a week, after which some soft food is given. They are allowed to resume use of the jaw gradually as the pain and swelling subside.

Case Reports

Following are reports of 6 cases operated upon using this technic.

Case 1.—Miss A. C., aged 20, was operated upon on May 20, 1937. She had a history of gradually increasing pain in the left jaw for the past six months, but no trauma. Pain on eating was referred up into the temporal region. She had clicking in the jaw when she was talking and snapping when she was ready to go to sleep at night. Examination showed snapping on opening the jaw and a clicking was felt on the left side on palpation. She had been examined by a dentist, who reported no trouble.

The operation lasted fifty-five minutes. Local anesthesia was used. A linear incision was made, the joint was opened, and the disk was found to be loose and doubling back on itself when the jaw was moved. The disk was excised and the strip of temporal fascia brought down and attached below the condyle with chromic catgut sutures.

A head bandage was applied to hold the jaw in place, but had to be removed the second day because of swelling and pain. Recovery was uneventful. Check-up one year following revealed no complaints.

Case 2.—Mrs. M. O., aged 31, underwent operation on October 19, 1937. She had had many abscessed teeth in childhood, which were extracted. She had suffered no trauma and no dislocation. For the past three years the patient had had pain in the left temporal mandibular joint, referred to the ear. Ear examination showed no pathology. A snapping noise had been present for two months. During 1936 she noticed that the jaw slipped forward on the left side, and the patient massaged it back herself. There had also been some pain extending from the right orbit to the occipital. Examination showed that the jaw subluxated on the left side on opening the mouth, but could be reduced easily by light massage. There had never been any locking. There was also crepitus, which was felt on moving the jaw. Planograph x-rays showed a shallow joint.

The operation lasted one hour and thirty minutes under local anesthesia. A straight incision was made. The zygomatic fascia was split forward almost to the temporo-zygomatic joint. The parotid was turned down with the facial nerve. Some small zygomatic branches of the facial nerve had to be cut. When the joint was opened the cartilage was found to be intact and was not removed. A shelf was turned down in front of the articular tubercle and held in place by a wedge of bone from the zygoma, deepening the articular fossa. A strip of temporal fascia was sutured to the condyle to re-

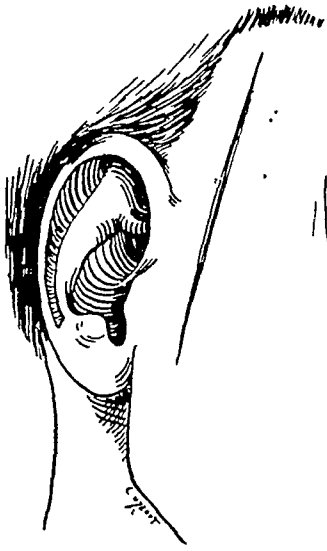

Fig. 3A

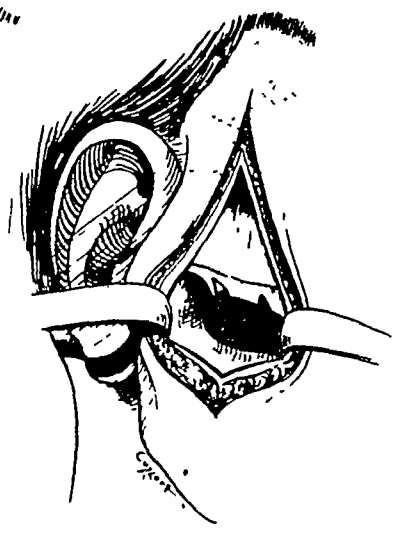

Fig. 3B

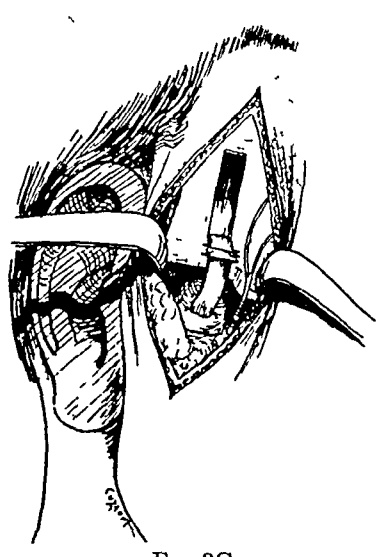

Fig. 3C

inforce the joint. A bandage was applied to immobilize the jaw but had to be removed on the fourth day because of swelling and pain. The patient had an uneventful recovery. One year after operation there was still some diminution of wrinkling of the left side of the forehead. This was probably due to small motor branches from the facial nerve having been cut in the wide exposure. A stable jaw was present with no complaints of pain or clicking.

Case 3.—P. G., aged 52, was operated upon on April 8, 1938. He had complained of snapping in the jaw for two years, with pain referred to the right ear. There had also been a sense of tiredness in the right side of the face, with aching at night. He had had considerable diathermy and the joint had been injected twice with no relief. The patient had all his teeth removed. For two months he had been unable to sleep because of a loud snapping in the jaw. X-rays were negative. Examination showed that the patient was thin and the right temporal mandibular joint could be well felt. On opening the jaw the condyle rode forward and a loud snap occurred before the mouth was completely open A sixty-minute operation was performed. A straight local incision was made, the joint was opened, and the disk was found to be detached and frayed along the detached portion. Cartilage was excised and the temporal fascia attached to the condyle. No fixation was used. A check-up three months following showed still some pain on opening the jaw wide, but no clicking.

Case 4.—Mrs. S. M., aged 36, underwent operation on October 16, 1939. She had been in an automobile accident three months prior to admission in which she was hit on the left side of the head. Following the accident a snapping developed in the right jaw. She had had diathermy, massage, and a head bandage, with no relief. There was no history of locking in the joint. Examination revealed that the patient was quite stout; nothing was palpated, but on motions of the jaw a clicking noise was heard which was transmitted to the fingers on palpation. This referred pain into the right ear. X-rays were negative. A fifty-minute operation was performed under local anesthesia A linear incision in front of the ear exposed and opened the joint. The cartilage was doubled on itself into the back of the joint. The cartilage was removed and a strip of temporal fascia brought down to reinforce the joint No fixation was made. Recovery was uneventful and the patient was discharged from the hospital in ten days. There was no check-up, as the patient left the state.

Case 5.—J. M , aged 28, underwent operation on September 17, 1940. The patient had had a wisdom tooth extracted one year and a half before the operation. Following the extraction snapping developed in the right jaw. He consulted his dentist, who said that the occlusion was normal. He then tried chiropractic treatments and had a course of injections, with temporary relief. For two months prior to the operation, snapping became much more pronounced. The patient complained of temporal pain and earache. Examination showed a well-developed young man. Snapping and crepitus were present in the right jaw. X-rays were negative. A forty-five-minute operation was performed under local anesthesia. A straight incision was made, the jaw was opened, and the cartilage was found to be frayed and detached. The joint capsule was much relaxed. The disk was removed and a strip of temporal fascia was sutured to the condyle. A follow-up examination one year later revealed no clicking and no pain; the patient made no complaints.

Case 6.—Mrs. G. T., aged 44, was operated upon on December 9, 1940. Two years before she had

had two wisdom teeth removed. Following this there was persistent pain in the jaw which gradually became localized to the left; there was also earache on the left. She had been to several dentists, who had adjusted her occlusion with no relief. She then
[illegible] She stated that
r the left jaw and
ie left eye. Following these attacks she was unable to eat any solid food. Examination revealed a thin middle-aged woman. There was crepitus present in the left jaw, and when the mouth was opened wide a loud snapping noise was heard. This caused pain in the ear. The x-rays were negative. The operation was performed under local anesthesia and took fifty minutes. A straight incision was made, the joint was opened, and the cartilage was found to be frayed but not detached. The cartilage was removed and the temporal fascia ligament applied to the condyle. No retaining apparatus was used. The patient left the hospital ten days after the operation. A report from her physician in another state six months later mentioned no complaints.

Discussion

Dr. John W. Ghormley, *Albany*—The author is to be congratulated for presenting his opinion and experience upon this troublesome and controversial subject. Operative procedures upon the temporomandibular joint are looked upon, both by the laity and the profession, with considerable apprehension. And it is true that a majority of cases with dysfunction of this joint need not come to operation. The more reports we have of good results following operative procedures, the more intelligently we can deal with these patients.

I have made no attempt to review the literature, but I believe that the last important contribution on the subject was that of Dr. Mayer, who in 1933 reported doing his bone block in 3 cases. Nieden, in 1923, in the *Deutsche Zeitschrift für Chirurgie*, reported a case in which he turned down a piece of the temporal fascia and attached it to the condyle of the jaw. Apparently that is the procedure used by the present essayist. A third report was made in the *Archiv für klinische Chirurgie* in 1921 by Konjetzny, who in 3 cases took a portion of the posterior intra-articular cartilage and turned it forward and lodged it in the anterior half of the joint, in order to prevent forward slipping. The present author's report of six cases operated upon is a welcome addition to that list.

Dr. Otho C. Hudson, *Hempstead*—We would like to emphasize the pathologic changes.

There are two types of joint lesions. (1) The shallow mandibular joint giving subluxations is less frequently seen. (2) The pathology in the joint giving internal derangement may be thinning of the internal meniscus, partial destruction of the meniscus, or complete destruction of the meniscus. After complete destruction of the meniscus there occur roughening of the condyle and destruction of the articulating surface of the articular eminence; that is, traumatic arthritis of the joint. These changes can be seen in x-ray by the decreased density of the bone about the mandibular fossa.

The dentist, by correcting malocclusion, may relieve the patient with a thin meniscus of symptoms. The other patients need surgical intervention.

ROCHESTER ACADEMY ANNOUNCES PRIZES

The Rochester Academy of Medicine announces three prizes
1. The
by a ce
case history
officer of a
This award
of Mrs. Da...
Companies prize of $100, accompanied by a certificate of award, will be given for a thesis contributing to the knowledge of clinical medicine (including internal medicine, surgery, obstetrics, pediatrics, or other subdivision) attained by accurate observation of laboratory studies, and by deduction from accurate observation of cases, combination of these. Competition for this prize is open to any doctor of medicine whose degree was received from an approved medical school since April 30, 1940, and who is either a bonafide resident of Monroe County or is on the staff of a accredited medical institution located in Monroe County. The Paine Drug Company prize of $100, given for clinical surgery, review of the literature, laboratory studies, and public health survey, or a combination of these. Competition for the prize is open to any member of the Rochester Academy of Medicine in good standing on May 1, 1944.

The theses should be sent to the Rochester Academy of on or before March disclose the identity be attached a sealed envelope carrying this identification.—*J.A.M.A., Dec. 23, 1944*

Case Report

CLINICAL TREATMENT OF MENOPAUSAL HYPERTHYROIDISM WITH TESTOSTERONE PROPIONATE

ALEX GOLDMAN, M.D., ABRAHAM I. SCHAFFER, M.D., and MARK J. MARKHAM, M.D.,
New York City

SEXUAL phenomena in the female are characterized by their cyclic nature. The menstrual changes are only the outward manifestations of a wide variety of quantitative and qualitative chemical and cytologic changes that occur with a fairly regular periodicity. A definite variation in urinary estrins can be demonstrated at varying points in the menstrual cycle. Under normal and pathologic conditions Aron[1] has observed parallel variations in the excretion of the gonadotropic and thyrotropic hormones, and Hitchcock and Wardwell[2] have found a correlation between the metabolic rate and the blood estrin content. There can be little doubt that quantitative variations will ultimately be demonstrated for all the related endocrine secretions.

With the onset of the menopause, there is a gradual or sudden cessation of this periodicity. That there is a definite and immediate effect upon the pituitary gland is demonstrated by the appearance of large quantities of gonadotropins in the urine. Whether it is assumed that the ovary loses its capacity to respond to gonadotropic stimulation (end-organ failure), or whether the failure is primarily in the secreting mechanism of the ovary has not been determined. However, the end result is essentially the same—namely, an alteration in the production of the female sex hormones.

There occurs concomitantly a change in the activity of the anterior pituitary, for this gland has now lost the natural inhibitory influence of its interdependent relationship with the ovary. As has been stated, increased quantities of gonadotropins can be demonstrated in the urine. Similarly, increased quantities of 17-ketosteroids are excreted in the urine of menopausal women, indicating an excess of adrenotropic factor. It is difficult to definitely demonstrate an increase in the thyrotropic factor in the menopause. However, the frequent clinical occurrence of hyperthyroidism at the time of the menopause points to the possible presence of such an excess.

Inhibition of the pituitary by an estrogen would, therefore, appear to be the desired goal in any attempt to relieve the symptoms of hyperthyroidism associated with the menopause.

In an earlier report, we[3] described the use of large doses of estrogenic substances in the treatment of clinical hyperthyroidism at the time of the menopause. Of five cases of menopausal hyperthyroidism treated with progynon B, all showed both clinical improvement and lowering of the basal metabolic rate.

One of the patients (S. B.) had been given gonadotropic hormone (follutein) for several days through an error. Her basal metabolic rate increased from +50 to +69 per cent, and all her symptoms were aggravated. The resumption of estrogenic therapy resulted in clinical improvement and a slight decrease in the metabolic rate. In an effort to further decrease the metabolic rate, male hormone was substituted for estrogenic therapy with very satisfactory results. Another patient (B. M.), a 22-year-old woman, who had undergone two thyroidectomies, returned in January, 1941, complaining of aggravation of all of her symptoms. Although she had gained 45 pounds, her metabolic rate had increased to +11 per cent. After the administration of 10,000 units of gonadotropic hormone (follutein), her metabolic rate increased to +50 per cent. At this point estrogenic therapy was substituted, with a consequent fall in her basal metabolism to normal. These cases appeared to be evidence that in menopausal hyperthyroidism we are concerned with thyrotropic hormone excess, as Van Horn[4] and Sherwood[5] seem to have demonstrated. Gonadotropic hormone therapy results in stimulation of the production of thyrotropic hormone; estrogenic therapy results in inhibition.

Further investigation along these lines was thought to be necessary. Certainly, if the administration of testosterone propionate could produuc results comparable to those obtained with estrogens, another step would have been taken to indicate that we are dealing with a direct suppression effect upon the pituitary. Geist[6] has obtained a definite inhibition of urinary gonadotropins in postmenopausal women treated with testosterone propionate. Second, under certain circumstances, such as in elderly impotent men with a low basal metabolism, testosterone propionate can produce an elevation of the basal metabolic rate. Therefore, the clinical relief of the symptoms of menopausal hyperthyroidism, together with a fall in the basal metabolic rate and a decrease in urinary gonadotropin would lend support to the contention that the effectiveness of testosterone propionate therapy is due to an inhibiting effect upon the anterior pituitary.

It is for this reason that we wish to report upon the following cases of menopausal hyperthyroidism treated with testosterone propionate.

Case Reports

Case 1.—Mrs. S. B., aged 50 years, was admitted to the Bronx Hospital in December, 1937, complaining of gallbladder symptoms, weakness, and loss of 60 pounds in three years. She had had no menses in the past fifteen months. Her thyroid was slightly

enlarged and there was a fine tremor Her blood pressure was 180/100 and her basal metabolic rate was +49 per cent and +50 per cent on two occasions The gallbladder could not be visualized on x ray after oral dye This is the case in which chorionic gonadotropin (follutein) was given every day for seven days through a misunderstanding The patient's nervousness and tremor became worse and her metabolic rate increased to +69 per cent Then [illegible] 1 6 mg intra was substituted, 53 per cent and was discharged returned to her marked tremor and nervousness and a metabolic rate of +55 per cent Resumption of estradiol benzoate 1 6 mg three times weekly, resulted in a steady moderate improvement in her symptoms in the course of the next six months and her metabolic readings were +50 per cent, 44 per cent, and 31 per cent In October, 1938, the substitution of testosterone propionate (Oreton) therapy in doses of 25 mg three times weekly was started and her metabolic readings decreased to +12 per cent, 2 per cent, and 6 per cent [illegible] nths together No therapy 1941 Since her gallbladder symptoms were very much worse a cholecystectomy was performed at this time She then felt well until a year ago when she developed ascites due to cirrhosis of the liver and died

Case 2.—Mrs M M aged 52 was admitted to the Bronx Hospital in June 1941, complaining of epigastric pain, relieved by food and also of tarry stools Another hospital had made a diagnosis of duodenal ulcer after x ray During the six months of her illness, she had lost 32 pounds, suffered from insomnia and a chronic dry cough and her menses had become scanty Examination showed a flushed, [illegible] ectro- erapy +19 nt so striking that she resumed work

This case may be summarized as follows A woman in the menopause with symptoms predominantly abdominal was found to have a definite hyperthyroid condition Intensive estrogenic therapy [illegible] mptoms At the [illegible] ir fibrillation and [illegible] no decrease Then testosterone propionate was given with a very satisfactory improvement of her general condition and a marked and unmistakable fall of the basal metabolism rate

cholesterol 160 mg per cent, and there was occult blood in the stools [illegible] thick gastric rugae The tremor, nervous irregular menses we pausal hyperthyroid [illegible]

rate to +51 per cent, ment After the pat hospital clinic treatm weekly for six weeks, per cent and then +38 per cent, with marked im [illegible] substitution times weekly decrease of metabolic rate to +27 per cent, and, in May, 1943, to figures of +10 per cent and +9 per cent The patient is now feeling very well and has resumed work

Case 3.—Mrs R F, aged 46 years was admitted to the Endocrine Clinic of the Bronx Hospital in March 1941, complaining of cramp like abdominal pains after meals infrequent vomiting dyspnea on [illegible]

a pulse of 120, and blood pressure of 215/110 The abdomen was somewhat distended, but no masses or fluid were demonstrable The oral sugar-tolerance test showed decreased tolerance fasting sugar 129 mg per cent, one hour 233, two hours 266, and three hours 217 The basal metabolic rate was +47 per cent Treatment was started with estradiol benzoate 1 6 mg three times weekly After two weeks, auricular fibrillation developed and the liver was slightly enlarged, but treatment was continued After two more weeks there was subjective improvement, and this continued for six weeks more, with a gain in weight of [illegible] and no fibrillation high, 175/90 and +55 per cent Because of the persistently high metabolic rate, estrogenic therapy was stopped and treatment was begun with testosterone propionate 25 mg three times weekly After thirteen injections in eight weeks, her metabolic rate had decreased to +18 per cent No therapy was given for three months at which time the rate had risen to +28 per cent, the apex rate was 100, pulse 80 the blood pressure was 180/90, the liver was again palpable, and there was slight pretibial edema Resumption of testosterone therapy after eleven injections in five weeks showed a metabolic rate still high (+33 per cent), with dyspnea, palpitation, and definite

Summary and Conclusion

1 Three cases of hyperthyroidism associated with the menopause have been presented All three cases showed moderate improvement of their toxic thyroid symptoms and some lowering of the basal metabolic rate when treated with large doses of estrogenic substance (progynon B)

2 In all three cases improvement was maintained and increased when testosterone propionate in 25 mg doses was substituted for estrogenic substance (estradiol benzoate)

3 The nonspecific effective action of both estradiol benzoate and testosterone propionate in lowering the basal metabolic rate and improving the clinical state in these menopause patients who show hyperthyroid symptoms, and the opposite effect of chorionic gonadotropin in heightening the symptoms and raising the basal metabolic rate leads to the conclusion that we are dealing with a thyrotropic or thyrotoxic principle which is inhibited or suppressed when the pituitary is inhibited and which is stimulated when the pituitary is stimulated

We wish to point out that in some cases of menopausal hyperthyroidism in which estrogenic treatment is ineffective testosterone propionate will produce the desired effects

Secondarily, we have observed that prolonged treatment of these middle-aged menopausal women with testosterone propionate resulted in no voice changes and in no appearance of hirsuties. This is in direct contrast to the results noted in young women in whom testosterone has been employed.*

* The testosterone propionate used in these cases was supplied by Dr. Max Gilbert, of the Medical Research Division of the Schering Corporation, Bloomfield, New Jersey. The folleutin used in these cases was supplied by E. R. Squibb & Sons, New York City.

CONVALESCENT HOSPITAL CARE FOR POLIOMYELITIS CASES

The pooling of personnel resources to meet the great need for postacute and convalescent care of victims of this year's outbreak of infantile paralysis in New York State was given detailed consideration by hospital administrators at a meeting called September 26 by the State Department of Health.

Dr. Edward S. Rogers, assistant commissioner for medical administration on the department staff, in whose office the meeting was held, stated that according to the closest estimates that he could make the total number of cases in upstate New York will reach 4,000 by the end of the present outbreak, now past its peak, equaling the figure for the epidemic of 1916. This does not, however, hold true for New York City, the expected total for which is 1,800 cases, only about one-fifth of the number experienced in 1916.

After considering these estimates and the expectation that approximately 25 to 30 per cent of the total cases reported will require convalescent hospital care, the group expressed serious concern over the problem in future months of providing the facilities required to meet upstate demands.

Harold A. Grimm, past-president of the Hospital Association of New York State and a member of its Executive Committee, introduced a resolution, which was unanimously approved by those present, providing for the appointment by the State Commissioner of Health of an Advisory Coordinating Committee, to consist of three representatives of each of the following groups: The Hospital Association of New York State, the New York State Association of Institutions for the Physically Handicapped, and the New York State Department of Health. It will be the function of this committee to evaluate the needs of the postepidemic poliomyelitis period, make recommendations to the Commissioner of Health concerning the allocation of personnel and patients to institutions qualified to care for such patients and any other matters relevant thereto, and to urge the membership of their respective organizations to cooperate to the fullest extent in the program to be outlined.

Commenting on this resolution, Dr. Rogers said that such willingness on the part of all concerned to pool their resources of personnel and to assume to the utmost of their ability their share of the volume of cases to be handled constituted a most important step toward meeting this difficult situation.

He added that there was no question as to the availability of sufficient hospital beds in institutions adequately equipped to provide the necessary care; but that practically all of the institutions were insufficiently staffed to utilize their full bed capacity and that this deficiency, in the opinion of the group, was an extremely serious problem. Trained physical therapists and nurses are in greatest demand.

It is hoped that through the action of the committee to be appointed and the cooperation of such agencies as the American Red Cross, the National Foundation for Infantile Paralysis, and many other public-spirited groups, the resources for manpower in the State may be more fully utilized. The group was agreed that there are an appreciable number of qualified physical therapists and nurses, no longer active in their profession, who, if the urgent need were understood, would be willing to make the sacrifice of returning to active duty for short periods of time. Any such persons in the State are requested to communicate immediately with Dr. Rogers, State Department of Health, Albany 1, New York.

The group plans to appeal to appropriate departments and agencies in states throughout the nation in behalf of the New York State institutions where the need for this additional help is critical.

Dr. Rogers said that the shortage of personnel, not only of nurses and physical therapists but of hospital personnel of all categories, had been made acute because of the war. He added, however, that it was impossible to think that some way could be found, through public-spirited effort, to make available to children and older victims of the epidemic the type of care that they require now, and will continue to need during the course of the next six months or more, to prevent the development of serious deformities that could not otherwise be prevented.

Those attending the meeting were: West J. Altenburg, New York State representative of the National Foundation for Infantile Paralysis; Assemblyman Lee B. Mailler, first vice-president of the Hospital Association of New York State; Anastasia McConnell, vice-president of the State Association of Institutions for the Physically Handicapped; H. B. Meek, vice-president of the State Association of Institutions for Physically Handicapped; Moir P. Tanner, president of the State Association of Institutions for the Physically Handicapped; Dr. David D. Rutstein, deputy commissioner of the New York City Department of Health; Carl Wright, executive secretary of the State Hospital Association; and, from the State Department of Health, Dr. Leon Sternfeld, acting chief, Bureau of Medical Rehabilitation; Clifford Shoro, director, and Marion L. Henry, assistant director, Division of Accounts; Marion W. Sheahan, director, and Mattie M. Washburn, assistant director, Division of Public Health Nursing.—*Health News, October 9, 1944*

Case Report

CHICKENPOX, HERPES ZOSTER, AND ACUTE ANTERIOR POLIOMYELITIS

JOHN C. McGARRAHAN, M D , Cohoes, New York

THERE is a growing mass of evidence which points to a possibly fundamental relationship between herpes zoster and chickenpox Primarily, the evidence emphasizes the tendency of both conditions to appear concurrently in communities at times In addition, the characteristics of the individual lesion in both herpes and chickenpox are apparently identical, and each process is accompanied by some degree of pruritus or paresthesia such as identify milder forms of neuritis, although in herpes zoster severe pain is the rule

So far as I know, there have been no reports on the parenteral use of thiamine hydrochloride in chickenpox, though its use and high degree of efficacy in herpes zoster are relatively well known Therefore, the following cases are presented

Case Reports

Case 1.—J. G , a white boy aged 14, who had had chickenpox when he was 3 or 4 years old, was seen on January 8, 1942, with typical chickenpox of forty-eight hours' duration. The general symptoms and the extensiveness of the lesions were much more severe than usual Ordinary general and local measures were used, but on the following day a new crop of lesions was appearing, involving even the palms The temperature was still elevated and the

[illegible] hour was restless Then he announced that all of the itching had suddenly disappeared The following day he was found to be perfectly comfortable, having slept all night, and the lesions which had started on the previous day were already dry, while the older lesions were retrogressing As a measure of safety the dose was repeated. There was no reaction of any sort after this dose, and recovery was entirely uneventful.

Case 2.—J. N., a white girl aged 10, on March 15, 1943, developed chickenpox When seen the following day she presented multiple, scattered lesions in various stages of development, the larger blebs being surrounded by areolae a half inch in diameter. There was a profusion of beginning lesions Fifty [illegible]

March 18, all except the largest lesions were dry and the child was clinically well No further treatment was given and all scabs were off in ten days

Case 3.—D C , a white boy aged 8, developed chickenpox on June 23, 1944 He was first seen on June 24. He was not very ill and presented only a moderate number of characteristic lesions scattered over the body. His temperature by axilla was 99 F. Salicylates, catharsis, and antipruritic ointment were ordered When seen on June 25, at about 5.00 P M , he was not and had not been very ill but was quite uncomfortable from the intense generalized itching The lesions were much more numerous and

[illegible]

marked congestion of the conjunctivae but no jaundice The liver edge was palpable, rounded, and very tender He was given 50 mg each of thiamine, nicotinamide, and ascorbic acid intravenously. Shortly after 11:00 P.M. (about six hours after the parenteral dose) he fell asleep and slept soundly all night There was no further itching and no new lesions appeared His sister, aged 4, developed chickenpox on July 8 while away from home and consequently was not under my care. The mother reported later that this child had been quite ill with high fever, intense pruritus, and a profusion of lesions, some of which were apparently quite large. She commented on the marked difference in the course of the disease in the two children

These cases link more closely together chickenpox and herpes zoster through a method of treatment which has proved its worth in herpes and may be of extraordinary value in chickenpox, particularly in adults and older children, and, with modification of the mode of administration, in young children and babies. The general reaction noted in these cases with termination of the disease process six hours after the intravenous dose of thiamine hydrochloride coincides with the time lapse required for relief of pain by the same method in herpes zoster and neuritis of deficiency origin, in my experience.

Without reference to therapeutic management, the following interesting combination of pathologic processes is set forth

Case 4—T. S , a white boy aged 3, and A S , a 5-year-old girl, brother and sister, came down with chickenpox on November 17 and 18, 1942 On October 25, the mother had developed a head cold and shortly thereafter the father had developed a painful rash which, when seen on November 3, proved to be an extensive herpes of the right thigh. Some of the lesions were hemorrhagic. About this time the mother had become achy and had had an enterocolitis followed by a pulmonary process of both bases resembling early consolidation (virus

had an extensive herpes labialis, though she was otherwise apparently well.

A more startling combination of disease entities in the light of the facts set forth is represented by the following case:

Case 5.—S. R., a white man aged 28, became ill with a cold about August 29, 1941. He developed generalized aches and pains and his disease was diagnosed as "grippe" by a physician, who gave him salicylates and advised bed rest. I saw him on September 5, 1941, after he had been ill about a week. Temperature and pulse were both elevated. He had no cough but he complained bitterly of headache, which he "had never had in his life before," and of pains in his arms and legs. He was very irritable. There was stiffness of the neck and spine and soreness of the muscles of the arms and legs. He was unable to flex the right thigh on the trunk. Neoprontosil and thiamine hydrochloride were given by mouth. His fever subsided after four days. In this time soreness and weakness of the muscles about the left shoulder had appeared. He was referred to the Orthopedic Division of the State Health Department for follow-up after the subsidence of the acute phase, and their final report indicated complete recovery without residual disability.

On the third or fourth day from my first visit, his wife complained of a painful rash which she asked me to see. She had an extensive herpes intercostalis on the left side. She said that she and her husband had come down with colds at the same time and that after a few days of discomfort in the left side of her chest, the rash began to appear. About two weeks after the father was first seen, the baby, 7 months old and bottle-fed, came down with very mild chickenpox, characterized by relatively few but typical lesions and no general symptoms. The older child, 2 years of age, showed no signs of any illness. Both children were necessarily restricted in contacts because of the quarantine imposed by the father's illness and, so far as is known, neither could have been exposed to chickenpox.

It is difficult to look upon the practical coincidence of acute anterior poliomyelitis, herpes zoster (acute posterior poliomyelitis), and chickenpox in three members of the same household as more than an interesting group of clinical facts, but its possible significance cannot be ignored.

Finally, there is presented the following case. Although an isolated instance, it involves a therapeutic measure which is harmless in itself and was apparently of no little efficacy in this particular patient.

Case 6.—J. T., a white girl aged 8, had always been subject to gastrointestinal upsets characterized by vomiting, diarrhea, and fever, usually clearing spontaneously after a few days. She had no spells from December, 1942, until June 28, 1943, when she began with what appeared to the mother to be the usual type of upset. During a week of very hot weather she had been in a large swimming pool with her sisters, aged 3 and 10, on June 22 and 24. She had seemed perfectly well except for conjunctival redness noted by the mother on June 25. On June 27, the three sisters played for a considerable time under a running hose. The following morning the patient complained of not feeling well and of having a headache. Vomiting and diarrhea followed. She was feverish and continued to have headache. She did not complain of pains in any other part of her body, but she was irritable. I saw her on the morning of June 30, at which time she was obviously very ill. There were marked twitching of the facial muscles, irritability, and confusion. The lips were dry and cracked. The tongue was moist, protruded in the midline, and its tip was cherry-red. The pharynx and tonsils were normal in appearance. There was no abnormality of teeth or gums. The pupils were slightly dilated, reacting sluggishly to light. Eye movements seemed normal. There was a suggestion of bilateral ptosis of the lids. The ear drums were normal. The sclerae were slightly congested but not icteric. Axillary temperature was 105.1 F.; the pulse was 150. The neck was quite stiff and the back slightly so, with marked tenderness of the paravertebral muscles. The abdomen was slightly distended and sensitive, especially in the epigastrium. The knee-jerks were not elicited; the Kernig reaction was positive on both sides; the Babinski sign was uncertain; no ankle clonus was noted. The thigh and leg muscles were extremely tender. The patient was incontinent of feces. The picture was one of involvement of the central nervous system in a process accompanied by a severe gastrointestinal disturbance. In the presence of the characteristic tongue sign of niacin deficiency, severe diarrhea, and disturbed sensorium, the administration of niacin seemed the first essential. Then, because thiamine deficiency is accompanied by vomiting in many instances, but chiefly because I have leaned to the theory that its lack plays an important role in the neural damage in poliomyelitis, thiamine hydrochloride seemed indicated. She was accordingly given 50 mg. of thiamine hydrochloride and 150 mg. of niacin intravenously. In addition, a mixture of bismuth and belladonna was ordered, with 0.6 Gm. of sulfanilamide and B-complex to be given every four hours when vomiting had ceased. Routine enemas were ordered.

There was no further vomiting. A specimen of urine that evening showed 4 plus sugar.

The following day, July 1, the child was so materially improved (axillary temperature 101 F., pulse 100, markedly reduced irritability, absence of muscle soreness, no diarrhea nor vomiting, reduced rigidity of neck and back) that it seemed advisable to omit the parenteral dose of thiamine and niacin, and to depend upon oral therapy. The patient was seen on July 2, when it was found that the conditions noted on the first visit had returned in aggravated form and the improvement noted on July 1 had completely disappeared. In addition, she had been unable to void for twenty-four hours. Soreness was not found in the legs, but the muscles of the shoulder girdle were extremely sensitive, especially the pectoral groups. The axillary temperature had risen to 104.5 F., and the pulse rate was 150. There was some scleral jaundice. The original intravenous dose was repeated. The urine was found to be sugar-free when voided that evening. On July 3, the patient was better than at any time previously. She was quite relaxed—in fact, almost sluggish. There was ptosis of both lids. The tongue was almost normal. There was no muscle soreness. Temperature by axilla was 99.4 F., pulse 100. The rigidity of the neck and back was diminished greatly. The intravenous dose was repeated.

On July 4, the temperature by axilla was 98 F., pulse 90. The chin could be brought easily to within an inch of the sternum. The child was somewhat lethargic but very hungry. The ptosis of the

lids was still present No muscle paralysis could be found on such examination as was possible, but there seemed to be a general wasting of all the skeletal muscles in minor degree The intravenous dose was repeated On July 5, she was found to have normal pulse and temperature, and was much [illegible] re was idence while to be eg off the bed against gentle resistance Vitamin B complex, belladonna, and bismuth were continued

The patient was seen every few days and on July 14 was found in excellent condition Her appetite color, disposition, and energy were definitely improved Some scleral jaundice was present and she had vomited once on the morning of July 12 There was definite difficulty in lifting the extended left lower extremity The Orthopedic Division of the State Health Department corroborated the weakness of the left lower extremity and found some weakness of the muscles of the right forearm

By August 1 she was walking about and, except for a tendency to throw the left leg in walking, showed no gross evidence of neuromuscular damage Her mother considered that the girl's general condition, color, appetite, and disposition were better than they had been for a long time Her intake of vitamin B complex has been continued and, in view of her lack of serious residual disability and her improved general condition, she was permitted to go back to school on September 27, 1943

In reviewing this case there seems little room for doubt that it represents a definite case of acute anterior poliomyelitis, or that the parenterally administered thiamine and niacin were responsible for the excellent outcome The proof of the latter point lies in the improvement after the first dose, the relapse on failure to follow with a second dose in twenty four hours, and the resumption of progress to complete disappearance of acute symptoms after three successive doses

No general conclusion can be drawn from this case, except it be the time tried rule that it is more important to treat the patient than the disease

Summary

This paper concerns itself with further data which contribute to the accumulating facts pointing to an interrelationship between chickenpox and herpes zoster In addition, it presents a method of treatment (intravenous use of thiamine hydrochloride) which in the cases of chickenpox on which it was tried brought the disease to an abrupt end in about six hours Finally, it presents a situation suggestive of a relationship between chickenpox herpes zoster, and acute anterior poliomyelitis and a case of the last which made unusual progress on treatment with thiamine hydrochloride and niacin intravenously during the acute stage

Conclusion

The value of thiamine hydrochloride in the treatment of herpes zoster is well established Its value in treating chickenpox is strongly indicated here Its use as a therapeutic measure in infantile paralysis is an opportunity not to be overlooked in any acute case of that disease As a matter of exact fact, I believe that the niacin in the case presented may have been as important as the thiamine It is fair to assume, in view of our present-day knowledge of the role of thiamine in the maintenance of nerve function, that its importance is primary and that the sufferer from infantile paralysis in its acute stage faces a better prospect with an available (parenterally administered) excess of thiamine, rather than with a possible deficit The importance of parenteral administration of thiamine (and niacin) in the acute deficiencies such as appeared in the cases reported here cannot be overemphasized It is the *relative* deficiency of one or more elements of the B group of vitamins which I believe is the fundamental in all of the cases presented here The origin of such a deficiency may at times be obscure, but material in preparation will help to define a mechanism whereby vitamin B-complex deficiency may appear despite an adequate dietary intake

I would emphasize here the fact that *all* of the diseases mentioned are "virus" diseases and I presume to raise the questions, "Are viruses antivitamins?" or "Does relative avitaminosis B predispose to tissue damage by viruses?"

I am aware of the material covered in the editorial "B-1 Vitamin Hypoimmunity"[1] and feel that some better explanation will be found for the statistical results quoted than a stimulating effect on poliomyelitis virus by thiamine The results of the experiments would suggest the existence of some unconsidered factor which, in my opinion, would be the actual physical and functional state of the host at the time of or shortly after the introduction of the virus Finally, attention is called to the article "Treatment of the Acute Stage of Poliomyelitis" by Dr Conrad Wesselhoeft[2] His second case, though less fulminating, has a measure of clinical similarity to the last case described by me and the marked contrast in the course of the acute stage in the two cases definitely serves to emphasize the value of the parenteral administration of thiamine and niacin In particular, I would point to the fact that Dr Wesselhoeft's case required repeated catheterization, while my patient, after twenty-four hours' retention, voided spontaneously in about six hours from the administration of the second intravenous dose (*cf* interval required for relief in the cases of chickenpox)

MEDICAL GROUPS HOLD FEBRUARY MEETINGS IN CHICAGO

The National Conference on Medical Service Plans will meet in Chicago on Sunday, February 11 On February 12 the Annual Congress on Medical Education and Licensure opens A score of other small medical and allied groups will meet in Chicago during this fortnight

Medical News

Four-County Drive Planned to Fight Rheumatic Fever

THE need for a campaign to inform the public of all available knowledge of rheumatic fever and rheumatic heart disease was discussed by Dr. J. G. Fred Hiss, professor of clinical medicine at the Syracuse University College of Medicine, at a Teaching Day on the subject conducted on December 1.

Dr. Hiss outlined the organization of a demonstration area for New York State to be set up in the four counties of Onondaga, Cayuga, Cortland, and Oswego, to provide a complete program for combating the disease. The program will be extended to the rest of the State, Dr. Hiss said, after it has been successfully organized in these four counties. The proposed plan will be known as the Syracuse District Cardiac Program.

Dr. David D. Rutstein, Deputy Commissioner of Health of New York City, outlined the reasons for an adequate program against the disease. He enumerated the five reasons as being difficulty of diagnosis, the chronic nature of the disease, the wide prevalence of the disease, and the complexity of care necessary for patients.

Dr. Homer F. Swift, of the Rockefeller Institute for Medical Research, discussed environment as a cause of repeated fever attacks. He said that a low economic status, by creating bad housing conditions with crowded facilities, may be a definite cause for the disease.

During the year of 1938, Dr. Swift said, in New York City five times as many deaths were caused among children by rheumatic fever as by whooping cough, spinal meningitis, measles, diphtheria, and scarlet fever combined.

Dr. Swift also discussed methods at present available for the prevention of the disease, though some of them are not applicable to the population at large at the present time. These methods have been developed by the Army for the treatment of its members.

Dr. Albert D. Kaiser, of the University of Rochester School of Medicine, declared that effective treatment of rheumatic fever resolves itself into intelligent aftercare. He pointed out several effective methods to prevent recurrence of the fever attacks. Although several more recent methods have been discovered, he said, administration of sodium salicylate is still the most popular medicine among physicians. The presence of tonsils has not been proved to encourage recurring attacks, he declared, but their removal often lowers mortality by minimizing chances of streptococcus infection.

Dr. Kaiser stressed the importance of having a public convalescent home for patients suffering from the disease so that they may receive the proper aftercare. He urged the creation of such a home in Syracuse.

Dr. T. Duckett Jones, of the Harvard Medical School, declared that the disease seems definitely to be associated with "crowding," as shown by its prevalence in Army and Navy cantonments. Dr. Jones said it is also associated with streptococcus infections and usually follows in three or four weeks after an attack of sore throat. He emphasized the need for not neglecting throat infections and tonsillitis.

Several hundred medical students at Syracuse University, including a large proportion of men in uniform, and physicians from the four counties, attended the meeting in the lecture hall of the College of Medicine during the afternoon.

Hines Names Doctors to Aid Veterans in Treatment of Rare Diseases

BRIG. GEN. FRANK T. HINES, Administrator of Veterans Affairs, named on December 21 eight members of a fifteen-member medical panel which will advise on the treatment of veterans suffering from rare types of diseases encountered in faraway battle areas, as well as improvement of general practices in the treatment of veterans.

The other members of the panel are to be named, he said, as soon as acceptances are received. None has refused to serve, General Hines told newspaper men, but some of the advisers are recurrently working either abroad or in operations which cannot be interrupted immediately.

Dr. George Morris Piersol, professor of medicine at the University of Pennsylvania, is chairman of the group, and Dr. Roy D. Adams, clinical professor of medicine at Georgetown University, is permanent secretary.

The six others who have accepted appointment on the panel are as follows: Dr. John Alexander, professor of surgery and surgeon-in-charge, Section of Thoracic Surgery, University of Michigan; Dr. J. Burns Amberson, Jr., professor of medicine, Columbia University; Dr. George E. Bennett, adjunct professor of orthopaedic surgery, Johns Hopkins University; Dr. William F. Lorenz, professor of psychiatry, University of Wisconsin; Dr. Frederick W. Parsons, former Commissioner of Mental Hygiene, New York State; and Dr. Oliver H. Perry, professor of medicine, University of Pennsylvania.

Meyer and Shaw Get Mental Hygiene Posts

EUGENE MEYER, editor and publisher of the Washington *Post*, who also has a distinguished record in business and public service, was elected president of the National Committee for Mental Hygiene at a meeting of the Board of Directors at a luncheon in New York on December 14. Dr. Adolf Meyer, of Baltimore, who was instrumental in the original organization of the Committee and suggested its name, was its president in 1940–1943 and recently has been honorary president. Mr. Meyer, as president of the Committee, will also serve as chairman of the board of directors.

Mr. Meyer is the first layman to be chosen president of the National Committee in the thirty-four years since it was founded by the late Clifford W. Beers. In many capacities in recent years he has exerted influence to improve mental health and has been especially concerned with mental health of men in the armed forces.

Previous presidents of the Committee have been

Dr Henry B Favill, Dr Lewellys F Barker, Dr Walter B James, Dr Charles P Emerson, Dr Arthur H Ruggles, and Dr Adolf Meyer

G Howland Shaw, who retired recently as Assistant Secretary of State after a long career in diplomacy and who has been active in many social and civic enterprises, was elected president of the American Foundation for Mental Hygiene at its sixteenth annual meeting, also held at the luncheon Mr Shaw succeeds the late Dr Bernard Sachs, of New York

Mr Meyer, Lt Col Karl Menninger, and Dr Lawrence Kubie were elected as directors, and the following were re elected as directors Dr Karl M Bowman, Dr William [illegible] Dr Frederick [illegible] Tarumianz, and Dr [illegible] ank Fremont Smith and Col Leonard G Roundtree were elected by the Board as vice-presidents to serve with James R Angell and Dr William L Russell, vice presidents The Board also re elected the following officers Dr Adolf Meyer, honorary president, James R Angell and Dr William L Russell, vice presidents, Mrs Albert D Lasker, secretary, Harry Pelham Robbins, treasurer, James S Plant, chairman of the Executive Committee, and Dr Edward A Strecker, chairman, Scientific Administration Committee

Reduction in the Medical Corps of the Army

A MODERATE reduction in numbers of Army Medical Corps officers is necessary in order to remain within presently allotted ceilings, the Office of the Surgeon General has announced The need for medical corps officers in senior grades assigned to administrative duties is less acute than formerly

A board of officers recently appointed in the Office of the Surgeon General is carefully considering the physical and other qualifications of all medical corps officers of the various components of the Army and their essentiality to the war effort

As a result of this board's study, it is anticipated that a number of separations of the above group will occur in the moderately near future Regular Medical Corps officers will be accorded retirement privileges under the provisions of Section II, Ar 605-245, June 17, 1941, and Reserve, National Guard, and AUS Medical Corps officers will be given the opportunity of returning to the practice of medicine in a civilian status by relief from active duty or discharge —*Release from the Office of the Surgeon General, Dec 15, 1944*

Army Microfilms Medical Journals

THE microfilming service of the Army Medical Library is keeping Army medical officers at remote installations in e [illegible] the latest publsi

Starting with [illegible] 1943 the list of [illegible] to forty four covering the whole field of medicine These are filmed immediately upon publication Sent by air mail, military intelligence, or diplomatic pouch, the rolls of film are in the hands of medical department personnel all over the world within fifteen days

In addition to the medical journals, unpublished [illegible] cent development [illegible] n request are

The microfilm process saves approximately 95 per cent of shipping space One 100-foot roll, for example, holds about 1,300 pages, or from twelve to fourteen journals [illegible]

Four Members of Typhus Commission Decorated

A WARD of the United States of America Typhus Commission Medal to four members of the commission was recently announced by the War Department, as follows

To Col Harry A Bishop, Medical Corps, Medical Section, Headquarters Mediterranean Base Section

For exceptionally meritorious conduct in the performance of outstanding services from December 28 1943 to February 19 1944 at Naples Italy Colonel Bishop was placed on duty with the American Typhus Commission at Naples at the height of a typhus epidemic in that city As coordinating and executive head of its program he directed the training of military and civilian personnel in typhus control their organization into effectual teams and the securing of needed equipment and supplies The efficient manner in which this task was accomplished despite the lack of trained personnel and adequate supplies is reflected by the rapidity with which the disease was brought under control By his forceful leadership and application to duty Colonel Bishop aided materially in alleviating suffering and preventing what might have become a major catastrophe

To Capt Edward Harvey Cushing, Medical Corps, United States Naval Reserve

For meritorious service in connection with the work of the United States of America Typhus Commission On Captain [illegible] which Captain Cushing had made to the planning of the first overseas expedition of the United States of America Typhus Commission he added personal service of high order in his forceful and tactful administration of the activities of the commission during a difficult period at its first station in the Middle East

To Dr Alexander G Gilliam, senior surgeon, United States Public Health Service

[illegible] among native Egyptians During the latter part of 1943 he made surveys of typhus fever in India and in China While engaged in the investigation of scrub typhus fever in Burma [illegible]

To Dr. Fred L. Soper, field staff member of the International Health Division of the Rockefeller Foundation:

"For meritorious service in connection with the work of the United States of America Typhus Commission. As one of the original members of the commission, Dr. Soper contributed to the organization of its first expedition to Egypt and to the direction of its first field studies in typhus control In the latter part of 1943 and early in 1944, as head of the Rockefeller Foundation group in Italy, he cooperated with the United States of America Typhus Commission in stopping the outbreak of typhus fever at Naples. Dr. Soper placed at the service of the commission his many years of distinguished service in the administration and operative control of epidemic diseases."—*J.A.M.A., Dec. 16, 1944*

Army Recruiting Student Physical Therapists

THE Army has issued a call for women to become student physical therapists. After serving an apprenticeship in Army hospitals, those who qualify will be commissioned as second lieutenants in the medical department.

Applicants must be women under 38 who are college graduates with a major in physical education or biologic science. They must meet citizenship and physical requirements, and have no dependent children under 14 years of age.

Women who meet these qualifications may apply to the Civil Service Commission or the Surgeon General, U.S. Army, Washington, D.C., for appointment as student physical therapy aides with a yearly salary of $1,440. Upon satisfactory completion of six months' training in Army general hospitals, students become apprentice physical therapy aides at a yearly salary of $1,620, and serve a six-months' apprenticeship with emphasis on the treatment of war injuries. Appointments to this latter position are also available to students who have completed an approved six-months' course in physical therapy conducted in civilian institutions.

Those who complete their apprenticeship satisfactorily will be commissioned as second lieutenants with a yearly salary of $1,800, an allowance of $21 monthly for subsistence, and an initial clothing allowance. These officers will serve as physical therapists in the Army Medical Department, and will be assigned wherever needed in this country or overseas.—*Release from the Office of the Surgeon General, Dec. 15, 1944*

County News

Albany County

Dr. Arthur J. Wallingford was elected president of the county society at the annual meeting on December 13 in the Albany College of Pharmacy Auditorium. He succeeds Dr. John B. Horner.

Dr. Raymond G. Leddy was elected vice-president. Re-elected were Dr. Homer L. Nelms, secretary; Dr. Frances E. Vosburgh, treasurer; Dr. Emerson C. Kelly, historian.

Dr. Stanley E. Alderson, Dr. James S. Lyons, and Dr. Donald D. Prentice were elected delegates to the convention of the Medical Society of the State of New York, with Dr. Jacob L. Lochner, Dr. James A. Hogan, and Dr. Clarence A. Traver as alternates. The following were elected members of the board of censors: Dr. Horner, Dr. James W. Bucci, Dr. John J. Clemmer, Dr. Edward P. McDonald, and Dr. Conrad A. Rissberger.*

• • •

Lt. Col. C. Stuart Welch, former assistant attending surgeon on the Albany Hospital staff, is the hero in a story from Germany about a miracle of front-line surgery during the peak of the United States Ninth Army battle along the Siegfried line.

The story, written by International News Service Correspondent Frank Conniff, says Colonel Welch removed an inch-long shrapnel fragment from the heart of an American officer.

The delicate ninety-minute operation was performed by Colonel Welch while the wounded officer's heart lay exposed. The surgeon later said it was the first of its kind among "thousands" of cases handled on the front since D-day.

The patient, the report states, is recovering and will suffer no permanent effects from the rare piece of surgery. The results are even more remarkable in light of the fact that the wounded man carried the fragment in his heart more than twelve hours before going under the surgeon's knife.

Col. Welch was assistant professor of surgery at Albany Medical College in 1937.*

Bronx County

The regular meeting of the county society was held at Burnside Manor on December 20 at 8:30 P.M. The program consisted of an executive session, followed by a lecture, "Recent Advances in the Treatment of Diabetes," by Dr. Elliott P. Joslin, with discussion by Drs. Samuel Gitlow and Frederick W. Williams.

Broome County

The annual dinner meeting and election of officers of the county society was held in the Binghamton Club on December 12 at 6:30 P.M., Dr. Frank G. Moore, of Endicott, the retiring president, announced.

Speaker at the affair was Andrew Spurgeon Beshore, an author, traveler, and humorist, of Harrisburg, Pennsylvania. Former director of vocational rehabilitation for the State of Pennsylvania, Mr. Beshore discussed "Antidote for the All-American Headache."

Wives of members of the society serving in the armed forces were guests.

The names of the new officers will appear in a later issue.*

Chautauqua County

The monthly meeting of the Jamestown Medical Society was held at the Hotel Jamestown on November 30. A paper on "Heart Disease" was read by Dr. Peter Vitanza and discussed by Dr. Frank P. Goodwin. A resolution was unanimously adopted urging the appointment by the City Council of a full-time laboratory director.*

Dutchess County

Dr. Edgar F. Powell, of Fishkill, has been appointed Dutchess County deputy medical examiner.

Dr. Powell is familiar with the processes of law-

New York County

The following editorial, entitled "Hail and Farewell," appeared in the December 23 issue of the County Journal:

"The present issue of the *Journal* of the Medical Society of the County of New York will be the last presented by the Society under the present title and format. The next issue of our publication will appear on January 5 under the title *New York Medicine* and with the subtitle 'Official Publication of the Medical Society of the County of New York.' Thereafter, *New York Medicine* will be published on the fifth and twentieth of each month throughout

the year. It will offer several new departments of interesting and valuable reading matter and comment on current affairs.

"In general, the editorial policy of the Journal will be carried forward without spectacular alteration in *New York Medicine*. However, it is planned to develop gradually a working editorial board representative of various aspects and institutions of medical practice. Through this board we hope to present a lively and progressive commentary on the current problems, opportunities, and responsibilities confronting New York physicians.

"As 'the old order changes, yielding place to the new,' we bespeak for your new publication the same degree of interest and support for which the editors of this Journal are profoundly grateful."

• • •

The detailed policy contract of the United Medical Service, Inc., the health insurance plan organized under guidance of the medical profession, received the official approval of the Medical Society of the County of New York at its meeting on December 18.*

A 73-year-old self-taught bacteriologist and serologist—fifty years ago a $17-a-month porter, scrubbing floors and windows and polishing brass for the New York Eye and Ear Infirmary—was honored on December 13 for his achievements in science.

Dr. Edgar B. Burchell, bacteriologist and attending serologist of the New York Eye and Ear Infirmary, was appointed Honorary Fellow in the American Academy of Ophthalmology and Otolaryngology, the largest medical association of eye, ear, nose, and throat specialists in the world. He will be the first person without an M.D., the first layman to be so honored.

At the ceremony in Weeks Hall, Dr. Burchell also received a gift and a jubilee award from the members of the hospital.

Though he is known as Dr. Burchell by his colleagues who are themselves M.D.s, he has never had more formal education than that supplied in the primary grades of New York City public schools. He has been called doctor since 1936 when he received the honorary degree of Doctor of Science from Roanoke College, in Salem, Virginia.

Dr. Burchell is regarded as especially expert on eye and ear diseases. In 1931 when the former King Prajadhipok of Siam came to the United States to have a cataract removed from his left eye by the late Dr. John M. Wheeler, Dr. Burchell was called in as consulting bacteriologist. He made the preliminary examination of the conjunctiva to determine if the eye was bacteria-free and if it was safe to go ahead with the operation. The examination showed the conjunctiva was free from bacteria and the operation was successful.

Dr. Burchell now does general laboratory work, especially pertaining to eyes, ears, nose, and throat, has eight laboratory assistants, and works seven and a half hours each day. He also teaches at the Eye and Ear Infirmary.*

Onondaga County

Syracuse physicians head the staff of a U.S. Army general hospital set up in the European theater of operations which has become known not only as one of the first U.S. Army hospitals to function in the war zone, but as one of the most efficient, according to a censored dispatch from the public relations section of headquarters of a United Kingdom base.

Lt. Col. Richard S. Farr and Lt. Col. Wardner D. Ayer, both Syracuse physicians, organized a group of medical and administrative personnel which formed the unit, activated September 1, 1942, at Camp Livingston, Louisiana, under command of Col. A. W. Greenwell, of Cornwall-on-Hudson.

The unit received training at Camp Livingston and in a staging area, under command of Lt. Col. George W. McCoy, Jr., of Fairhaven, Mass., and then went overseas with Lieutenant Colonel Farr in command.

Lt. Col. Arthur B. Raffl, MC, of Syracuse, is chief of surgical service. Formerly a staff surgeon at Syracuse Memorial Hospital, Col. Raffl has coordinated the surgical service into one of the most efficient in the theater of operations.

Colonel Raffl, a veteran of World War I, pointed out that in this war the remarkable strides of medical science have given the soldier more than an even chance to recover from his wounds, and that there is almost no gas gangrene type of infection, so prevalent in the other war.

The orthopaedic section, headed by Maj. John B. Stevens and Capt. George M. Kirkwood, Syracuse surgeons, has created an outstanding record for orthopaedic surgery in this theater, according to the dispatch.

Lt. Col. Tyree C. Wyatt, MC, chief of laboratory service, who formerly taught pediatrics and pathology at the Syracuse University Medical College, has introduced new laboratory technics in blood transfusions and pathologic procedures. Lt. Col. Ayer also formerly taught at the medical school and, since his arrival overseas, has lectured at the University of Birmingham and at many British meetings.

Lt. Col. Foster C. Rulison, chief of x-ray service, also serves as chief consultant for a base section in the zone. Col. Rulison, a graduate of Syracuse University College of Medicine, with his assistant, Capt. David W. Brewer, instituted a photo laboratory in connection with the x-ray service.

The dental clinic, supervised by Lt. Col. H. Membrey Roblin, who served at Camp Upton in World

War I as a first lieutenant, is one of the busiest clinics in the hospital with outpatients as well as regular patients.

The eye, ear, nose, and throat clinic is headed by Maj. Gordon D. Hoople, who also serves as consultant to an army hospital center in England and as unit historian.

Maj. Philip R. Chase, MAC, the hospital's registrar, has charge of all patients' records, and his department has drawn high praise for its careful handling of wounded coming in on hospital trains.

The detachment commander, Lt. James T. Cross, has gained the confidence and unqualified cooperation of the entire detachment by his leadership and understanding of enlisted men of the unit.

"The hospital's record of achievements in the European theater of operations," the dispatch ends, "can be summed up in one word—cooperation. Every officer, nurse, and enlisted man, from the commanding officer to private, takes a personal pride in the appearance, reputation, and record of of the unit."*

Ontario County

"Medicine After the War" was discussed by Dr. C. W. Grove at the second of a series of meetings of the men of the North Presbyterian Church held on November 28. Theme of the series is "Geneva After the War."

He cited the probable advance in control of malaria, pointing out that soldiers in this war have had greater protection from malaria than was ever before available. Although in the United States proper the disease is rarely encountered, except in some of the Southern States, 40 per cent of the human race is affected by its ravages.

The speaker advocated a modified form of socialized medicine, and the topic proved most controversial in a lively discussion from the floor, which followed the formal address. Refreshments were served after the meeting.*

Canandaigua Medical Society met on December 1 in the Canandaigua Hotel, with Dr. D. A. Eiseline, of Shortsville, as host.*

Orange County

The one hundred thirty-eighth annual meeting of the county society was held on December 10 at Bob's Village Inn, Montgomery. Dr. Walter I. Neller, the retiring president, presided. Officers for 1945 were elected. They are: president, Dr. George E. Kenny, Port Jervis; vice-president, Dr. Ralph Waldo Thompson, Cornwall-on-Hudson; secretary-treasurer, Dr. Earl C. Waterbury, Newburgh; censors: Drs. Hugh M. Brewster, Port *Jervis, William J. Hicks, Middletown, Charles W.* Layne, Newburgh, and Homer L. Stephens, Walden; delegate to the State Society, Drs. Theodore W. Neumann, Central Valley; alternate, Dr. Charles B. Reed, Newburgh; delegates to the First District Branch, Drs. Neller, Middletown, and Earl R. Van Amburgh, Pine Bush.

The speaker of the evening was Dr. Robert S. Cleaver, of Brewster. Dr. Cleaver is medical consultant on welfare cases in Putnam County, where the plan has been in operation for the past year.

Many interesting points of the plan were discussed by Dr. Cleaver and Dr. M. A. Stivers, of Middletown, who has recently been appointed to a similar position in Orange County.

Otsego County

The following is a list of the 1945 officers of t county society as elected on December 13, 19 president, Dr. Charles H. Peckham, Jr., Coope town; vice-president, Dr. Paul Von Haesel Gilbertsville; secretary, Dr. Marjorie F. Murr Cooperstown; treasurer, Dr. John M. Constanti Oneonta; censor, Dr. Norman W. Getman, O onta; delegate to the State Society, Dr. Mahlon Halleck, Worcester; alternate delegate, Dr. Pe ham.

Queens County

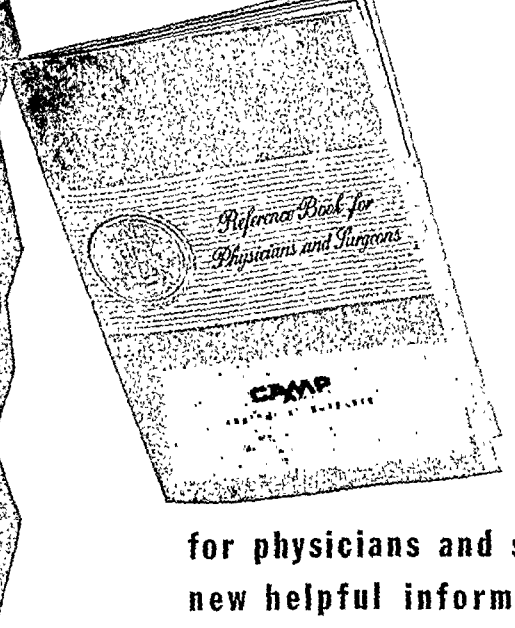
Dr. Vincent Juster, of Jamaica, was nam president-elect of the Queens Medical Society at t annual meeting held on November 28 in the Medi Building, Forest Hills.

Dr. Edward V. Veprovsky, of Flushing, nam president-elect last year, now becomes preside succeeding Dr. W. Guernsey Frey, of Forest Hills.

Other officers of the society elected were: sec tary, Dr. Ezra A. Wolff, of Forest Hills; assi ant secretary, Dr. Leo Goldberg, of Jamaica; tre urer, Dr. Arthur A. Fischl, of Long Island Ci assistant treasurer, Dr. Lawrence M. Waterhouse, Jamaica; historian, Dr. Joseph S. Thomas, of Flus ing; directing librarian, Dr. Alfred Angrist, Jamaica; assistant librarian, Dr. Anoch Lewert, Jamaica; trustees, Drs. Thomas M. D'Angelo, Jackson Heights, Walter Lynn, of Ridgewood, a Daniel J. Swan, of Flushing; censors, Drs. John Lowry, of Flushing, Meyeron Coe, of Queens V lage, Louis A. Sarrow, of Rockaway Beach, a Henry A. Reisman, of Jamaica; State Socie Delegates (two years): Drs. Frank Cerniglia, Forest Hills, Goodwin A. Distler, of Woodhave Joseph D. Hallinan, of Richmond Hill, W. Guerns Frey Jr., and Juster—(one year)(Dr. Erwin Bec hard, of Flushing, Dr. Joseph Wrana, of Jamai and Dr. Fischl.

Dr. Juster, the president-elect, is a surgeon. D Veprovsky, the incoming president, is a gynecol gist. He formerly practiced in Astoria.*

Schenectady County



The following officers were elected for 1945 at t annual meeting of the county society, December 1 president, Dr. D. Glen Smith, Schenectady; vic president, Dr. William E. Gazeley, Schenectad secretary, Dr. Nelson H. Rust, Scotia; treasure Dr. Alfred S. Grussner, Schenectady; delegate (tv years), Drs. Charles F. Rourke, Schenectady, Jam M. Blake, alternate, Schenectady; censors: Dr James J. York, Schenectady, Harry E. Reynold Schenectady, and Garrett M. Clowe, Schenectad compensation committee, Drs. William E. Gazele Edwin M. Stanton, Philip Parillo, Scotia; delega to the Fourth District Branch, Dr. Ralph D. Rei Schenectady; alternate, Dr. Ralph E. Isabell Schenectady.

• • •

The Medical Society of the County of Schenectad has joined other groups and individuals seeking th establishment of a mental hospital and clinic i Schenectady County. In a communication read a the monthly meeting of the Board of Supervisors o November 14 the society urged the board to act o the matter and offered its full cooperation in th establishment of such an institution.*

PROGRAM ON TRAUMA AND CARDIAC DISABILITIES

The New York Cardiological Society announces the inauguration of a project to study the role of trauma in the causation of cardiac disabilities. The work is planned as a continuing series of investigations and reports, with subcommittees on clinical statistics, on experimental investigation, on pathology, and on the medicolegal aspects. The general objective of the entire research is to study all angles of the relationship between trauma and heart disease and to formulate, on the basis of the widest investigation possible, a reasonable code for the guidance of expert opinion.

The project grew out of a suggestion of Dr. Raphael Lewy, Chief Medical Consultant of the Workmen's Compensation Bureau of the New York State Department of Labor. Dr. Lewy, now retiring after active service of over thirty years, said that expert opinions have shown such wide variance that it is of paramount importance for some dispassionate and competent body to examine all evidence in the literature and conduct such investigations as will produce a set of reasonable criteria that will have authority and general acceptance.

Funds for the work are being provided out of the Society's treasury and by various grants. An introductory meeting is planned for January 24, 1945.

All interested organizations, practicing physicians, and officials are invited to participate in the program or in the discussion. The meeting will take place at the New York Academy of Medicine; communications should be addressed to the secretary of the society, Dr. Philip Reichert, 480 Park Avenue, New York 22, New York.

N. Y. U. OFFERS POSTGRADUATE COURSES

The New York University College of Medicine has announced that it will give three postgraduate courses, starting in February, 1945:

1. Internal medicine—under the direction of Clinical Professor Charles H. Nammack, director of the Fourth Medical Division of Bellevue Hospital, and associates.

2. Clinical gastroenterology—by Assistant Clinical Professor Zachary Sagal. This course is designed for practicing physicians who wish to review the subject and acquaint themselves with the recent advances made in this field. The medical treatment and differential diagnosis of gastrointestinal conditions will receive special attention. The lectures will be preceded by demonstration on patients in the wards.

3. Arthritis and rheumatic disorders—by Assistant Clinical Professor Otto Steinbrocker and his staff.

For further information communicate with the Secretary of the New York University College of Medicine, 477 First Avenue, New York 16.

WHEN THE *Body Rebels* AGAINST THE DICTATES OF THE YEARS

The natural estrogenic substances, parenterally administered by the physician, not only appear to be more effective in overcoming adverse menopausal symptoms, but contribute psychotherapeutically by necessitating personal contact with the physician. Semestrin, derived from pregnant mares' urine, hence containing estradiol as well as estrone, proves as economical as it is effective, in the menopausal syndrome, gonorrheal vaginitis in children, senile vaginitis, frigidity.

SEMESTRIN

Semestrin, in 1 cc. ampuls is available in the following potencies: 2,000, 5,000; 10,000; and 50,000 International Units; 2,000 and 10,000 International Units per cc. in 30 cc. vials, and 10,000 International Units per cc. in 10 cc. vials.

Health News

Some Dividends from Communicable Disease Control in the Westchester County Health District*

TO ATTEMPT to evaluate public health activities by means of statistical proof of definite accomplishments is extremely difficult. This is so because personal and public health are intangible values that cannot be weighed or measured. Moreover, changes may be very gradual and are seldom the result of a single cause. In no other field of endeavor are comparisons so treacherous. This is true not only when the comparison concerns different places but also the same place at different times.

Communicable disease control activities are especially difficult to evaluate since in addition to the many variable factors involved the results are largely of a negative character. We know who has diphtheria or typhoid fever or smallpox but we do not know who would have had one of these diseases but for the efforts of the medical profession and the health authorities. There are diseases like smallpox and diphtheria means for the virtual extinction of which are available. Our knowledge of the prevention of some of the other diseases is not so complete. All we can hope to do with some of them is to attempt through isolation and quarantine to shield the individual from an attack until a possible natural immunity has developed or to postpone the attack in young or sickly children until they are better able to withstand it. Who these protected individuals are we do not know; they cannot be counted. We can pick over a barrel of apples and remove the rotten ones but we cannot tell which or how many of the sound apples would have become decayed had not the rotten ones been removed.

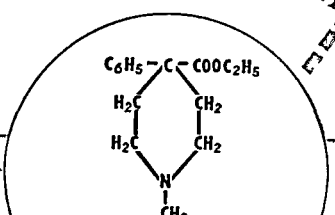
For smallpox and diphtheria we have specific means of prevention the extent of the employment of which can be gauged and the results measured in a rough way. During the ten years 1930–1939 approximately 25,000 individuals, mostly children, were reported to have been vaccinated against smallpox. This does not represent the total number vaccinated, since many vaccinations no doubt were performed by private physicians but never reported. Most of the vaccinations on record were performed in health department clinics. During the same ten-year period there were but three cases of smallpox in the health district. Two of these were found to have been contracted outside the State by a father and son who had visited relatives in a community where smallpox was prevalent. The other patient contracted the only secondary infection to occur in our health district. Prompt, effective quarantine plus the many vaccinations performed at that time and in previous years undoubtedly were instrumental in controlling the spread of the infection.

Diphtheria is another disease that lends itself readily to control through quarantine measures and to prevention through artificial active immunization. During the ten years from 1930 to 1939 slightly over 40,000 children were reported to have received the diphtheria immunization treatment. Here again the number is not complete, representing for the most part children treated in health department clinics. Prior to the organization of the health department in 1930 a large number of these treatments had been given, but mostly to school children, whereas the disease had been much more fatal in the preschool group. By 1934 it was estimated that 60 per cent of all children in the health district between 6 months and 5 years of age had received the diphtheria immunization treatment. By 1938 this percentage had risen to 70. It has since been increased to 72. What has been the effect of all this preventive work on diphtheria during this period? In 1929 there were 130 cases and 8 deaths attributed to that disease in the health district. The average annual number of cases for the five years 1925–1929 had been 125. In 1939 there were but 5 cases with no deaths. While the numbers of cases have varied between one and 9 per year since then, there have not been any diphtheria deaths.

With the improvement in our environment and in our water and food supplies, typhoid fever is fast becoming a relatively rare disease. In 1930 there were 48 cases in the health district. In 1939 there were 11. Since then the yearly total has been as low as 2. The few scattered cases that continue to occur are due in most instances to food prepared by a typhoid carrier for private consumption, often in the same home. During the first ten years of the health department 17 newly discovered typhoid carriers were picked up through the efforts of the staff and placed under constant supervision. Prior to 1930 there were only 6 known carriers in the district. By 1939, allowing for deaths and removals, the number had increased to 20. Not one of these carriers is known to have been the cause of a single case of typhoid fever in the health district since he or she was discovered and placed under supervision.

Among the communicable disease activities carried on by the department is a consultation service for diagnosis when the nature of the illness is in doubt. The records of this type of service, which are incomplete for 1930, show that during the ten years from 1930 to 1939 approximately 1,500 cases of suspected communicable disease were seen by department physicians for diagnosis.

In neither measles nor whooping cough can the dissemination of infection be effectively controlled. This fact is due, among other things, to the high degree of susceptibility prior to an attack, the extreme ease with which the infection is communicated, and the occurrence of a prodromal period of several days in both diseases during which the nature of the illness may not be recognized but during which it is very infectious. In addition to these obstacles to the control of infection in those cases that are reported, there are many other missed cases—i.e., cases that for one reason or another are not brought to the attention of the health department and in which little or no control is exercised.



The medical profession and health authorities have, therefore, had to fall back on efforts to limit the mortality which in both measles and whooping cough is greatest during the first three or four years

of life. During the ten years from 1920 to 1929 there were 82 deaths from measles and 117 from whooping cough. The corresponding figures for the following decade are 26 and 46, respectively. Moreover, this decrease occurred in the face of a rapidly increasing population that in 1925 was 217,000, and by 1935 had mounted to 300,000.

Undulant fever, a disease that can be controlled by improving the sanitary quality of the milk supply, appears to be becoming less prevalent as local herds of cattle are freed of Bang's disease and larger percentages of milk are pasteurized. During the first five years of the health department's first decade 20 cases of undulant fever were reported. During the second half of the decade there were but 10 cases.

Canine rabies was unduly prevalent in the health district in 1936, when the number of cases increased from 5 the previous year to 55. From 1936 to 1939, inclusive, there were 151 cases. During the previous four years there had been but 13. Little can be done to control the spread of the infection among dogs because of the difficulty in securing enforcement of the necessary control measures. Every effort has been made by the department, however, to prevent the development of human cases by furnishing antirabic vaccine free of charge to all who need it and by making sure that everyone bitten by or in contact with a rabid animal receive the necessary medical care. Despite the large number of rabid animals in the health district during the past few years, there has not thus far been a single case of human rabies since the organization of the health department.

FOR YOUR INFORMATION

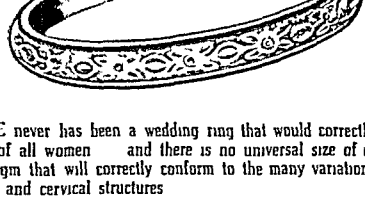
Thirty-four thousand nurses have now been classified in New York State. These include 2,200 recent graduates, of which one-third are available for military service.

As of September 1, 1944, 24,735 Army nurses were on duty overseas. Nurses are serving on twenty-four hospital ships, thirty-one hospital trains; also in air evacuation both in the United States and overseas. Promotions through the year totaled 5,968.

The National Nursing Council for War Service has been requested by the New York State League of Nursing Education to be the sponsoring agency for the intensive, "on-the-job" head-nurse courses being given throughout the State. At present, eight "trainers" who participated in the workshop held at Teachers College on "Materials and Methods of Head-Nurse Instruction" are conducting courses for head nurses in their own institutions. Some of these have invited head nurses from schools of nursing in the area to enter the course. Most plan to repeat the course and several expect to commute to other areas where there is a need for head-nurse instruction. At least one New York State nurse is attending a workshop at Catholic University and will join the list of "trainers" in the near future.

At present, another workshop is being held at Teachers College. This one is for "trainers" of supervisors and instructors in schools of nursing and public health agencies.

The State Nursing Planning Committee has had one meeting. A subcommittee is at work outlining objectives of the Planning Committee and assembling information on any nursing objectives now under way, planned, or needed, that relate to those objectives.



A total of 12,554 students are enrolled in New York State schools of nursing this year as compared with 8,826 in 1941.—*Minutes of National Nursing Council for War Service, September, 1944*

A MESSAGE TO NURSES—FROM FRANCES PAYNE BOLTON

"One thing I know," reports Mrs. Frances Payne Bolton in the January, 1945, *American Journal of Nursing*, after a two-months' visit to hospitals of England and areas of France which have been liberated, "were I fit and young enough and trained nothing would keep me from meeting the greatest challenge American life has ever given women who are nurses. If I were trained in nursing or physical therapy or as a nurse's aide and unable to go overseas I would apply for service in our hospitals here to which these men of ours are coming by the thousand. I wouldn't miss the experience altogether. I wouldn't go into it just because of the terrible need our wounded have for care: I would do it partly because I know I couldn't face myself in the years that inevitably come, when one looks back on life, if I had let the opportunity to live deeply pass me by.

"Yes, I have had a rich experience but an infinitely richer one awaits you who are trained, you who are young. The Army, the Navy, and the veterans hospitals, all of them need you, but the Army most of all. I say 'the Army'! But it is the men that need you—your men—who have thrown themselves against the most fiendish enemies that decent, clean, wholesome living has ever known. It is your own men who look to you consciously or unconsciously, knowing that wherever women are, trained women most of all, there can be found the new courage, the fresh hope, and the renewed faith they need to carry on the war and to face the hard road back to normal living."

There is no *Universal Size*

THERE never has been a wedding ring that would correctly fit the finger of all women and there is no universal size of occlusive diaphragm that will correctly conform to the many variations of the vaginal and cervical structures

Competent clinical investigation has established that an occlusive diaphragm must be of individually correct size in order for the cervix to be properly protected against entrance of spermatozoa

Because of the variance in the vaginal anatomy of individual patients the correct size can be determined only through measurement by a properly qualified physician

To insure closer more accurate fitting with greater comfort for your patients specify RAMSES™* Flexible Cushioned Diaphragm on your prescriptions

Ramses FLEXIBLE CUSHIONED DIAPHRAGMS

are made in gradations of 5 millimeters in sizes ranging from 50 to 95 millimeters in clusive available through any recognized pharmacy

Extension of Insulin Shock Therapy in State Institutions for Insane Recommended by Commission

A new type of treatment of the dementia praecox form of insanity, known as insulin shock therapy, which was devised by Dr. Manfred Sakel and brought to this country from Vienna in 1936, should be made available to praecox patients in all the State hospitals for the insane, the Temporary Commission on State Hospital Problems recommended in a report submitted to Governor Dewey on August 26.

The report was presented by Homer Folks, Chairman of the Commission.

The recommendation was based on the results of an intensive study made by the Commission of 1,128 dementia praecox patients treated with insulin shock therapy at the Brooklyn State Hospital in five and a half years and a comparable group of 876 patients admitted to State hospitals in the metropolitan area who did not receive that form of treatment.

"The insulin treated patients did substantially better in all respects than the nontreated patients," the report stated.

The tests used in measuring the effectiveness of the treatment were the subsequent ability of patients to leave the hospital and return to normal living at home; the length of hospital stay before leaving; the length of time patients were able to remain at home, and the extent to which they were restored to usefulness.

The report revealed that 79.5 per cent of the insulin treated patients were able to leave the hospital, as against 58.8 per cent of the nontreated group, and after a shorter stay. At the end of the study, between five and a half years and six months after release, 58.9 per cent of those who had received the shock treatment were at home, compared with 44 per cent not so treated. 55 per cent of the insulin patients were useful members of the community, in contrast to 40.5 per cent of the nontreated patients. Many were earning their living or more, and some were getting along better than before they became ill.

To put the findings into effect the Commission recommended that the State Department of Mental Hygiene make the new treatment available to all dementia praecox patients, unless they are not eligible for it for physical or other reasons, "unless and until other forms of treatment have demonstrated still better results."

The Commission stressed the importance of more effective treatment of dementia praecox because one of every four new patients admitted to the State hospitals suffers from that type of disorder, and since large numbers of them remain for protracted periods they comprise between 50 and 60 per cent of all the patients in those hospitals.

The report estimated that the insulin treatment in the Brooklyn institution had "effected a saving of 286,695 days of hospital care, a saving of $80,274.60 in cost of food and clothing, a substantial though undetermined saving in maintenance costs, and a still larger saving, ultimately, in construction costs."

The Commission recommended that to secure a consistent use of insulin therapy throughout the State hospital system a Consulting Service be established in the State Department of Mental Hygiene to assure adequate records; to hold consultations with hospital staffs in the interest of high standards of treatment, to make follow-up studies, and to provide special courses at the State Psychiatric Institute and Hospital for training personnel to administer the treatment.

The report stated that qualified and experienced social workers should be made available in each hospital in the ratio of one such worker to 60 patients to provide adequate supervision and aid to patients who have received shock therapy and are on parole or in family care.

The report now before Governor Dewey is the second submitted by the Temporary Commission since its appointment in November, 1940, to survey the continually growing population of nineteen State mental institutions caring for approximately 80,000 patients. In a "progress report" submitted to Governor Lehman in November, 1942, the Commission recommended not only extension of shock therapy but increasing the number of patients placed on parole or in family care. It reported that increased effort in these directions had not only halted the rate of increase of patients in the State hospitals, but during a four-month period in 1942, the long-standing average increase of about 2,400 patients a year had given place to a decrease of 78. This was the first such reversal in fifty years of State care of the insane.

The study, under the direction of the Commission, containing experts in the care and treatment of mental disorders, was made largely through personal visits by trained and experienced psychiatric social workers to patients and their families after becoming familiar with the hospital records. Mrs. Minna Field was director of research. A lengthy and comprehensive report, with detailed statistical and other data, gives the results of the study.

"The finding that the highest percentage of improvement, immediate or long range, occurred among those in whom the illness was of short duration . . . . might be utilized in achieving even better results with insulin therapy if something could be done to help identify patients in the early stages of the illness. . . . .

"Even among those groups in which the gains are minimal, either as to the length of time they are able to remain out of the hospital or the level of usefulness they attain, they are sufficiently positive to warrant the giving of insulin because of the benefit derived by the patient, his family, and the community, and the savings effected in hospitalization costs.

"The insulin-treated group was more heavily weighted with patients whose illness was of longer duration and who consequently had a poorer prognosis. Had we been able to match the numbers exactly, the substantially better results shown among the insulin-treated patients would have been even more striking."

Members of the Commission are Homer Folks, Secretary of the State Charities Aid Association, *Chairman;* Stanley P. Davies, Ph.D., Executive Director of the Community Service Society of New York; Miss Hester B. Crutcher, Director of Social Work, State Department of Mental Hygiene; Dr. Lawrence Kolb, Assistant Surgeon General, U.S. Public Health Service; Dr. Nolan D. C. Lewis, Director, New York State Psychiatric Institute and Hospital; Dr. Frederick W. Parsons, former State Commissioner of Mental Hygiene; Dr. William L. Russell, consulting psychiatrist, Payne Whitney Psychiatric Clinic, The New York Hospital; and Dr. George S. Stevenson, Medical Director, National Committee for Mental Hygiene.

TO SUPPLEMENT *Your Hydro-physiotherapeutic* FACILITIES

Hundreds of physicians send their patients in need of hydro- and physiotherapeutic care to Sylvan Baths — where, under experienced direction appropriate treatment is administered with a wide range of the most modern equipment including Galvanic Medicated Baths, Whirlpool, Sulfur, Nauheim and Oxygen Baths, also diathermy, massage and colonic irrigation

Your patients, whether suffering from arthritis, neuritis, high or low blood pressure, nervousness, insomnia, fatigue or any of the many other conditions amenable to the benefits of physical medicine, may greatly profit from the prescription of a visit to Sylvan Baths

Industry Plans Assimilation of Disabled Veterans

American industry in a joint program with the War Manpower Commission is girding itself to assimilate wounded veterans into jobs that the disabled would never have been considered capable of handling before, Chairman Paul V. McNutt announced on September 13.

In a pioneer move rapidly becoming nationwide, 2,000 employers in four leading states are analyzing close to two million jobs with a view to measuring their physical demands with the capacities of disabled veterans.

This was Mr. McNutt's first report on the adoption by industry of W.M.C.'s Selective Placement program for the employment of handicapped veterans.

States in which employers are taking the lead are Connecticut, Pennsylvania, California and Michigan. Maryland has similar plans and so have many other states. Employers participating include such major West Coast shipyards as Bethlehem Steel, Todd Shipyards, California Shipyards, U.S. Naval Drydocks, with the Kaiser plants in Oregon cooperating. Large employers in the East and Midwest interested in this movement include Westinghouse, General Electric, United Aircraft, Electric Boat, American Cyanamide, Carnegie-Illinois Steel, Aluminum Corporation, Hershey Chocolate, Crown Can, Ford Motor, Chrysler, Cadillac, Eaton Manufacturing, Radio Corporation of America, Armstrong Cork, and many others.

"Employers are enthusiastically accepting the new job-analysis approach as an excellent tool for industry in placing disabled veterans," Mr. McNutt said. "Under the system, jobs are analyzed in relation to the twenty-seven activities that have now been established as covering the whole field of jobs—for example, walking, handling, fingering, lifting, reaching, seeing, hearing, and so on. Most jobs actually only require a few of these activities. If the physical appraisal of the man shows that he can perform these, he is considered as fit as any able-bodied man for the job. The system is radically different from the guess method used after the last war.

"The key is not what the veteran can't do, but what he can do."

The program was introduced to industry, Mr. McNutt said, through employer institutes, consisting of groups of employers, representatives of personnel and medical departments, and shop foremen meeting in designated plants for training sessions on selective placement. Classes watched job-matching demonstrations at plant machines, often with the disabled veteran giving the demonstration.

Courses were also given, under the tutelage of W.M.C. occupational specialists, at the University of Michigan with the Automotive Council for War Production cooperating, the Detroit Institute of Technology, Michigan State College, University of Connecticut, University of California, and the University of Southern California.

In California the movement has been backed by the Merchants and Manufacturers Association. In Connecticut Selective Service has collaborated. Support has been given by the Veterans Administration, state rehabilitation agencies, the medical profession, churches, schools, businessmen's organizations, and social agencies.

Examples of how job-matching has helped returning disabled veterans whose talents might otherwise be wasted were given by Mr. McNutt. He cited the case of a Hollywood photographer who enlisted in Pearl Harbor at the time of the bombing, and later lost his leg. "Physical demands analysis of his old job," Mr. McNutt said, "showed that it called for walking, standing, stooping, and kneeling to pose his camera and get the right angles. It was out of the question for him to resume it. The U.S. Employment Service found that a newspaper wanted a photographer to receive photographs over its photo-wire system. This requires full use of the hands but in no way calls for any of the capacities this man lost to the Japs. He got the job."

Mr. McNutt also cited the case of a young man in Connecticut who won the Distinguished Service Cross for heroism in the South Pacific, but who lost his left arm in the doing. Upon his return he was put to work as an inspector in a wire-insulating factory, but doing visual inspection only. Under the job analysis approach it was possible to promote him to final inspector of very fine wire, extremely important work which involved special skill in micrometer and gauge reading and which, it was discovered, could be done with one hand. This man did such a good job that later he was made foreman.

"The success of our disabled veterans pioneering the way for the other combat wounded is proving that there is no beneficence in their employment," Mr. McNutt said. "They deliver full value, sometimes outproducing the fellow employee who has no physical disability. The families of our heroes who have come through can rest assured that they will have every chance to make good in the normal working world."

Cities in which W.M.C.-employer institutes have been held are Philadelphia, Pittsburgh, Lancaster, Altoona, York, Reading, Allentown, Easton, Erie, Chester, Scranton, Greensburg, Williamsport, Pennsylvania; Hartford, New Britain, Waterbury, Wallingford, Menchen, New London, Meriden, Bristol, Connecticut; Detroit, Lansing, Muskegon, Michigan; Los Angeles and San Francisco, California.—*Release from the Office of War Information*

HEART ASSOCIATION TO HOLD SESSION

The New York Heart Association, a division of the New York Tuberculosis and Health Association, will hold a scientific session on Friday, January 26, at 8:30 P.M. at the New York Academy of Medicine according to an announcement made by Dr. J. Burns Amberson, president.

Dr. Reginald H. Smithwick, associate visiting surgeon, Massachusetts General Hospital, and instructor in surgery, Harvard Medical School, will speak on "The Surgical Treatment of Hypertension." Drs. William Goldring, James W. Hinton, and Bronson S. Ray will discuss the subject. Dr. Harry E. Ungerleider, associate medical director, the Equitable Life Assurance Society, will speak on "Cardiac Enlargement—Its Recognition and Significance," and Dr. Marcy L. Sussman will open the discussion.

Where Nutritional Failure Complicates— SECONDARY ANEMIA

IN MANY CASES secondary anemia is accompanied by other signs of nutritional failure. Most frequently encountered as a complication is B complex deficiency. In such cases Hebulon* Capsules offer you a convenient means of attacking both phases of your therapeutic problem.

Hebulon contains not only iron in the readily assimilable ferrous form, but also crystalline vitamin B_1 and liver extract as well. Each Hebulon Capsule contains 2 gr. of exsiccated ferrous sulfate (approx. 40 mg. iron), 50 U.S.P. units of vitamin B_1, and liver extract derived from 16 gm. of fresh liver.

Hebulon thus provides a convenient means of supplying not only iron, but v min B_1 and the anti-anemic substances c tained in liver extract, which have b shown to be frequently needed in case nutritional failure.

Hebulon is supplied in bottles of 100, and 1000 capsules.

* "Hebulon" (Registered in U. S. Patent Office) is a mark of E. R. Squibb & Sons.

HEBULON

Pulmonary Tuberculosis Associated with Congenital Heart Disease

It is commonly accepted that individuals suffering from congenital heart disease are prone to develop and later to succumb to pulmonary tuberculosis. Of all patients with congenital heart anomalies it is those with pulmonary stenosis who seem most likely to develop tuberculosis. Whether it occurs more frequently in this group than among a comparable number with normal hearts cannot be stated positively without detailed statistical analyses. Case reports seem to show that tuberculosis is no greater menace in patients with pulmonary stenosis than is their cardiac defect.

It is true, however, that many persons born with this anomaly die before they have relatively much opportunity to develop tuberculosis, many of them being so incapacitated that they are protected from infectious contacts. If predisposition does actually exist, it must arise primarily in the faulty oxygen and blood exchange characteristic of these cases.

This study concerns the frequency of congenital heart conditions in a tuberculosis institution, the course of the pulmonary disease, and the efficacy and advisability of collapse therapy in the face of the cardiac handicap.

In the course of 1,545 necropsy examinations of tuberculous individuals, seven cases of congenital heart disease were discovered, an incidence of 0.4 per cent. This incidence may be higher than in most other tuberculosis institutions due to the fact that one out of eight beds in this hospital is allotted to pediatrics. It is lower than that observed in institutions devoted entirely to the treatment of children.

The diagnosis made from the symptoms and physical examination of six additional patients coincided unusually well with the defects found in the seven cases that came to autopsy. They exemplify the grouping of cardiac anomalies known as the tetralogy of Fallot. A picture of this condition is represented by this composite case report: The patient is a white youth in his lower teens. The history records cyanosis from birth or shortly thereafter, and the diagnosis of congenital heart disease was made early. At that time the child was placed on restricted activity and followed in a hospital outpatient department. He has had no evidence of congestive failure and has led a fairly normal life until the onset of the pulmonary disease. Examinations show a young-appearing, underdeveloped child not, as a rule, dyspneic, but with cyanosis and clubbing of the fingers and toes. The heart is enlarged in all dimensions, with a loud, harsh, systolic murmur at the base, usually associated with a systolic thrill. The lung findings are dependent upon the pulmonary pathology. Laboratory tests indicate a well-marked polycythemia and there are tubercle bacilli demonstrable in the sputum. Roentgenography and fluoroscopic examination demonstrate enlargement of both ventricles, frequently more marked in the right, and a prominent pulmonary conus. The venous pressure is within normal limits and the blood pressure tends to be normal or slightly decreased. In the electrocardiogram are found right axis deviation and tall P waves, these often being notched. The pulmonary disease has not influenced the findings typical of the combined heart lesions making up the cyanotic group.

The onset of pulmonary disease in these cases was similar to that of patients without congenital heart disease. Some or all of the usual symptoms of tuberculosis were present in all cases. No difficulty was experienced in differentiating between the congenital heart disease and pulmonary tuberculosis, since the congenital anomaly was diagnosed in all cases prior to the onset of the tuberculosis. The disease was moderately or far advanced on admission to the hospital in all but one case. The course of the disease and the lesions at autopsy were similar to those observed in patients without the cardiac hazard. The duration of life depended upon the extent of the disease on admission and the effectiveness of collapse therapy when that was used. The longest duration in the series of 13 cases was six years, the shortest courses were seven months. The average duration of life from the onset of the pulmonary infection to fatal termination was one to two years.

As the lesions and other factors of the pulmonary infection are the same whether or not the patient has congenital heart disease and as the cause of death depends upon the pulmonary rather than the cardiac status, it is the lung rather than the heart which should be the focal point of therapy. When bed rest fails to arrest the progression of the tuberculous infection or cannot accomplish cavity closure it must be supplemented by collapse therapy in spite of the cardiac pathology. When this procedure is adopted late in the course of the disease the possibility of arresting the tuberculosis is slight. The life expectancy of these patients even without the pulmonary complication is short. Nevertheless, therapeutic measures, even hazardous ones, seem justifiable if they will prevent the patient from succumbing even more prematurely to tuberculosis.

In the group of cases here reported pneumothorax was instituted in five cases. In one case only was an effective pneumothorax established. In no case did collapse therapy increase the cardiac symptoms or lead to congestive heart failure.

It is recommended that congenital heart disease should not be considered a contraindication to thoracoplasty and in order not to deprive these patients of the few years of life expectancy due them, immediate operation may be more advantageous than a preliminary, often disappointing, trial of pneumothorax.—*The Development of Pulmonary Tuberculosis in Congenital Heart Disease, Oscar Auerbach, M.D., and Marguerite G. Stemmermann, M.D., Am. J. M. Sci., Feb., 1944. Tuberculosis Abstracts, August, 1944*

WOMEN FURTHER MEDICAL SERVICE

A campaign to obtain a 100 per cent enrollment of Nassau County physicians in the United Medical Service, Inc., is now under way among members of the Woman's Auxiliary of the Nassau County Medical Society. Following an address by Dr. Frederick Elliott, Medical Director of United Medical Service, at a meeting of the auxiliary, the members voted to acquaint local physicians and their wives with the aims of the service by making personal visits to their homes, talking to those too busy to attend county meetings, and distributing literature. The campaign is being conducted under the leadership of Mrs. Grace V. N. Van Kleeck, president of the auxiliary.

Woman's Auxiliary

To the Medical Society of the State of New York

County News

Nassau County. Lighted candles adorned the window ledges of the Nassau Hospital auditorium for the annual Christmas party of the Woman's Auxiliary of the Nassau County Medical Society in Mineola. Mrs. Louis A. Van Kleeck, of Manhasset, presided; and Mrs. E. Freeman Miller, of Freeport, chairman of program, introduced the entertainers.

Miss Leona Davis, of Freeport, played the vibraharp, accompanied at the piano by Miss Elma Ventress. Their selections were "Silent Night," "Liebestraum," and "White Christmas." Mrs. Gordon Asmundsen, of Hempstead, led in the community singing of Christmas carols.

Mrs. Miller then introduced the "Wo Aux Players," who appeared in an original Christmas play, in pantomime, with Mrs. Arthur C. Martin, of Old Westbury, as the commentator. Taking part were Mrs. August Fincke, Garden City; Mrs. Spencer B. Caldwell, Baldwin; Mrs. Clymer A. Long and Mrs. Eugene J. Miele, Freeport; and Mrs. Percival A. Williams, of Garden City. Mrs. Williams directed a spelling quiz.

Mrs. John L. Neubert, of Roslyn Estates, and her hospitality committee served the refreshments.

Instead of the exchange of gifts which featured such events in the past, members brought packages containing gifts for children, which will be delivered to boys and girls in foster homes in the county.

The executive board met on January 11. The next auxiliary meeting will be on January 23.

HEALTH DEPARTMENT RELEASES DATA ON CITY'S CRIPPLED CHILDREN

There are now well over 17,500 known cases of crippled and otherwise orthopaedically handicapped children in New York City. This fact was revealed in a survey of orthopaedically handicapped children released on December 26 by the Division for Physically Handicapped Children, a unit of the New York City Health Department's Bureau of Child Hygiene. Based upon Health Department figures as of June 30, 1944, the report shows that prenatal influences and injuries associated with birth, poliomyelitis, cerebral palsy, and clubfoot, in that order, rank highest among the causes of disability. These figures are being sent to approximately one hundred organizations and individuals particularly interested in crippled children in the city.

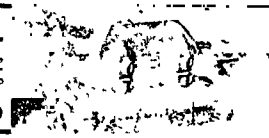
According to Health Commissioner Ernest L. Stebbins, a total of 17,578 orthopaedically handicapped children under 21 years of age were registered with the Division for Physically Handicapped Children as of June 30 of this year. The actual total, he stated, is probably somewhat higher since not all cases of handicapped and disabled children are reported to the Health Department.

The largest number of cases listed in the table—6,246—were caused by "prenatal influences and injuries associated with birth." Poliomyelitis, the second largest cause, accounted for the crippling of 3,914 children registered with the Division. "It is interesting to note," commented Dr. Stebbins, "that in June of 1939 we had 4,856 children on our register who had been crippled by poliomyelitis. This seeming decrease in 'polio' cases is probably due to the fact that many of the children who acquired their handicaps in the epidemic of 1935 are now over 21 and therefore are no longer listed on our register." Dr. Stebbins then warned that next year's register would probably show an increase in the number of poliomyelitis cases as a result of the outbreak which occurred in the summer and fall of 1944.

In addition to prenatal influences and injuries and poliomyelitis, the other major causes of disability listed include cerebral palsy (1,819 cases), congenital clubfoot (1,483 cases), and scoliosis—commonly known as "curvature of the spine" (1,474 cases).

The Division for Physically Handicapped Children, which prepared the tabulation, maintains a central registry of crippled children under 21 years of age in New York City and serves as an agency for coordinating and developing services for the prevention and treatment of physical handicaps in children.

"Orthopaedic cases, of course, represent but one of the many problems we must face in caring for our handicapped children," Dr. Stebbins stated. "Other comparatively common problems such as chronic heart conditions, faulty hearing, and defective vision are also being given careful consideration by the Health Department."



HOSPITAL SERVICE GIVES RADIO PROGRAMS

The series of radio programs sponsored jointly by the Greater New York Hospital Association, the United Hospital Fund, and the Associated Hospital Service of New York at 8:15 P.M. each Wednesday over WNYC will feature the following speakers for January, 1945: January 3—Bernard McDermott, superintendent, Long Island College Hospital; January 10—Dr. E. M. Bluestone, superintendent, and Dr. H. Houston Merritt, chief of the Division of Neuropsychiatry, Montefiore Hospital; January 17—John F. McCormack, superintendent, Presbyterian Hospital; January 24—Dr. Ernest L. Stebbins, Commissioner, Department of Health, New York City; January 31—Dr. Haim Yassky, executive director, Hadassah Medical Organization of Palestine.

Foundations of Neuropsychiatry. By Stanley Cobb, M.D. Third revised and enlarged edition of the work formerly known as *A Preface to Nervous Disease*. Octavo of 252 pages, illustrated. Baltimore, Williams & Wilkins Co., 1944. Cloth, $2.50.

REVIEWED

Guiding the Normal Child. By Agatha H. Bowley, Ph.D. Octavo of 174 pages. New York, Philosophical Library, Inc., 1943. Cloth, $3.00.

This book traces the normal growth and development of children from babyhood through adolescence. The author feels that the physical and intellectual factors concerned in child growth have been thoroughly worked out but that the emotional factor involving the growth of character and personality has been relatively neglected because it is more difficult to evaluate the latter in terms of standards. This has been remedied through the development of child guidance clinics.

The book may be read by physicians interested in understanding the psychologic problems associated with the growth of the normal child.

S. S. Lamm

Metastases (Medical and Surgical). By Malford W. Thewlis, M.D. Quarto of 230 pages, illustrated. Charlotte, N.C., Charlotte Medical Press, 1944. Cloth, $5.00.

This volume is an outline of metastases encountered in neoplastic and inflammatory diseases. In alphabetic and tabular form, according to disease, consideration is given to the site of origin of the primary process and the locations of secondary lesions. It does not give the relative frequency with which these metastases are encountered. This book would have been of greater value had the writer indicated which sites of metastases were most common, less common, and rare according to the various primary foci.

REORGANIZATION OF MEDICAL TRAINING IN GREAT BRITAIN

Word has been received from the British Information Services that the Interdepartmental Committee on Medical Schools has made the following recommendations that every medical school should be an integral part of some university, and grants from public funds for its educational work should be received through the university, that there should be more full-time appointments and salaries for clinical teachers, with an academic head for each clinical division, that postgraduate study should be encouraged as a feature of regular practice by refresher courses for general practitioners, along with regular association with hospitals and

to house special research units It is recommended that central health service councils be established with university representation on them that non-teaching hospitals have access to teaching centers, and that special centers, maintain refresher courses for general practitioners —*J A M A*, *Aug 19, 1944*

RADIOLOGISTS TO MEET IN FEBRUARY

The annual meeting of the American College of Radiology, scheduled to be held in Chicago in February, has been postponed because adequate hotel accommodations could not be obtained. Instead, there will be a Conference of Teachers of Clinical Radiology and a panel discussion, arranged by the Commission on Hospital Standards.

The Board of Chancellors will meet on Thursday, February 8, and Friday morning. Friday afternoon, February 9, the Commission on Education will conduct a Conference of Teachers of Clinical Radiology.

On Saturday morning, February 10, the Commission on Hospital Standards will present a panel discussion on "Radiology in Prepayment Plans." Spokesmen for radiology, Blue Cross, hospitals, and other interested groups will participate. Miscellaneous conferences will be held Saturday afternoon and in the evening there will be an informal dinner.

The meetings will be held at the Drake Hotel, Chicago, February 8–9–10.

MORRISON PRIZES AWARDED

The two annual A. Cressy Morrison Prizes of $200 each were presented December 14 to Eleanor G. Alexander-Jackson, Ph.D., member, research department of public health and preventive medicine, Cornell University Medical College, and Alexander Sandow, Ph.D., assistant professor of biology, Washington Square College, New York University, during the one hundred and twenty-seventh annual meeting of the New York Academy of Science at the American Museum of Natural History.

The New York *Times* reported that this is the first time in the history of the prizes that one of them went to a woman scientist. Dr. Alexander-Jackson was chosen for her work in discovering a "hitherto unobserved form of the germ causing tuberculosis," revealing the existence of what is known as the "zoogleal" form of tubercle bacillus. Dr. Sandow was selected for his paper reporting studies giving new light on the mechanism of muscular contraction. The Morrison Prizes are awarded "for the two most acceptable papers in any field of science, within the scope of the Academy and its affiliated societies."

Walter H. Bucher, Ph.D., was elected president of the Academy of Science. Dr. Florence R. Sabin, member emeritus of the Rockefeller Institute for Medical Research, was elected an honorary life member, the first woman scientist to be thus honored by the Academy.—*J.A.M.A., Dec. 30, 1944*

DR. WADE HEADS POLIO FUND DRIVE FOR NEW YORK TEACHERS

The chairmanship of the New York school teachers' division of the 1945 fund-raising appeal of the National Foundation for Infantile Paralysis has been accepted by Dr. John E. Wade, Superintendent of Schools, it was announced on January 1 by Basil O'Connor, president of the Foundation.

"A bill of rights for children," said Dr. Wade, "must include the right of those who are handicapped physically to receive the necessary care and treatment so that they may live a life as nearly normal as possible. The work that the Foundation does in fighting one of the most devastating diseases of childhood is close to the heart of every educator and will be supported by the teachers."

The March of Dimes campaign will begin on January 14. Benefit balls honoring President Roosevelt's birthday will be celebrated on January 30.

ADDITION OF NEW MEXICO TO ROCKY MOUNTAIN MEDICAL JOURNAL

Arrangements have recently been completed, by which the *Rocky Mountain Medical Journal* will be the official journal of the New Mexico State Medical Society.

Dr. Carl Gellenthien, of Valmora, New Mexico, will be the editor for the State of New Mexico.

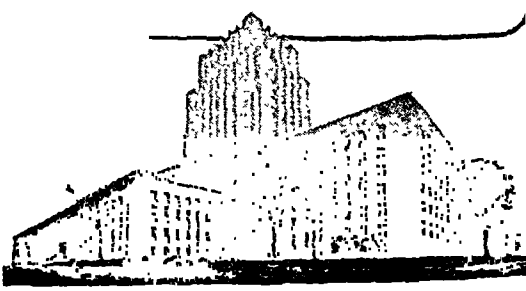
when a small amount of ooze is fatal



In neurosurgery, where a small amount of ooze makes the difference between success and fatality[1], fibrin foam has been hailed as one of the greatest advances in hemostasis. It affords quick control "of oozing from small vessels," from "large superficial cerebral veins," and from the "beds of tumors."[2]

FIBRIN FOAM

is a dull, porous, spongy substance which can be rapidly and simply cut to the desired shape and size and easily prepared for direct application to the oozing surface by saturation in the thrombin solution supplied with it. It is a product of human blood plasma, developed at Harvard University. The Upjohn Company is privileged to be associated with the production of fibrin foam and thrombin. *Not available for sale*

WALLACE & TIERNAN

Natural Vitamins

IN MASSIVE DOSAGE FOR CUTANEOUS AFFECTIONS

Whether the beneficial results obtained with Apolarthron in certain skin affections are due to a direct pharmacodynamic action or merely to the correction of a vitamin deficiency and its cutaneous manifestations, is yet to be determined. The fact remains that its administration in adequate dosage (3 to 4 capsules daily) rapidly produces notable results in acne, psoriasis and keratosis follicularis (Darier's disease).

A rapidly growing bibliography attests to the efficacy of both vitamins A and D in high potency, as found in Apolarthron, for the effective treatment of these skin diseases.

BOMBING MISSION (medical version)

TARGET FOR TODAY...not Japs, but *rats*...mosquitoes...flies...disease-carrying insects and vermin that infest the steaming jungles of the Pacific.

For this is a *bombing mission in white!* The "bombs" are loaded not with T.N.T., but more likely with D.D.T. which, sprayed from the air, seeks out and kills the adult mosquito and fly.

Yes, with D.D.T., with the aerosol bomb and countless other new developments in sanitation and disease control, the soldiers of medical science are proving themselves fighting men through and through. And, like so many other fighting men, they find pleasure and cheer in a few moments relaxation with a cigarette. Probably a Camel for, according to actual sales records, Camels are the favorite with smokers in *all* the services.

Camels *Costlier Tobaccos*

MARINOL

(IMPROVED FORMULA)

MARINOL (*IMPROVED FORMULA*) is an homogenized emulsion of cod liver oil and vegetable oils fortified with fish liver oils of high vitamin A potency to which has been added pure vitamin D_3.

OUTSTANDING PROPERTIES

PALATABILITY: The desirable properties of the fish liver oils have been retained without the disagreeable taste and odor.

HOMOGENIZATION: This assures a uniform and stable product that permits of easy miscibility with milk, special formulae, fruit or vegetable juices, or with water.

HIGH VITAMIN POTENCY: 5,000 U.S.P. units of vitamin A and 500 U.S.P. units of Vitamin D_3 supply the daily minimum requirements (FDA) in one teaspoonful.

LOW COST: A single teaspoonful daily is a prophylactic dose.

FOOD VALUE: Fish liver and vegetable oils supply another desirable property—that of caloric value.

EASY ADMINISTRATION is possible because of unusual potency of small dose.

CONSUMER PRICE: Bottle of 6 fl. oz. 85 cents. Bottle of 12 fl. oz. $1.50 (M.P.R. 392). HOW SUPPLIED: Bottles of 6 fl. oz. and 12 fl. oz.

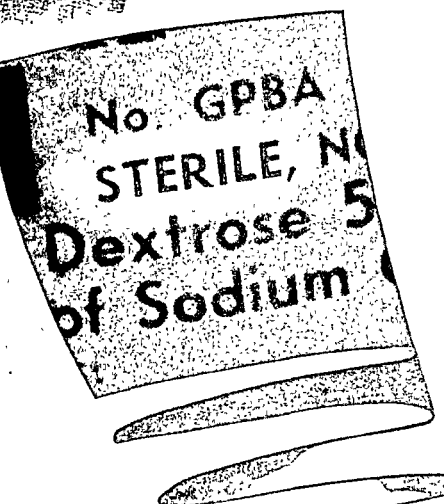
FOOTWEAR



for **CORRECTIVE TREATMENTS**

No animal laboratory tests can supply information as a guide to the proper choice of therapeutic footwear. Only the hard-earned experience gained over a generation of fitting shoes to all conditions of feet, and learning from the experience of individuals in all age groups who have not been fitted properly before, can provide the essential knowledge adequate for manufacturing and fitting helpful shoes.

Add to this the recommendations of specialists in medicine and you have a dependable source for beneficial footwear that supplements your treatments of any member of the family.

ANOTHER Baxter SAFEGUARD

"containing no micro-organisms"

On every Baxter Vacoliter the reassuring word "sterile" appears. Baxter Solutions, tested with scientific certainty before shipment to you, are kept sterile by the Baxter Vacoliter. Baxter Transfuso-Vacs, Centri-Vacs, and Plasma-Vacs are similarly tested and their sterility insured.

Such safeguards, and Baxter's simple, convenient technique contribute to a trouble-free parenteral program. No other method is used by so many hospitals.

'Alka-Zane' weather...

Weather maps and your jangling telephone denote the season of increasing incidence of diseases requiring sulfonamide therapy . . . and 'ALKA-ZANE'* Alkaline Effervescent Compound. Given in water as a refreshing drink, 'ALKA-ZANE' Effervescent Compound provides the two primary safeguards now known to be essential in avoiding sulfa drug crystalluria and its renal complications: (1) Elevation of urinary pH, thereby increasing the solubility of sulfonamides and their conjugates to help prevent their precipitation in the urinary tract. (2) Increased fluid intake and urinary output—to minimize further the possibility of crystalluria.

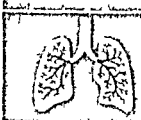
ETHER-IN-OIL
(Brewer)

AN ADJUVANT
IN THE TREATMENT OF
BRONCHIAL ASTHMA

Definite results in recently treated acute bronchial asthma cases, have proven the beneficial properties of ETHER-IN-OIL used in conjunction with other standard medications.

Six patients, having had an attack of acute asthma from two to five days, were thus treated (Dr. Maietta, *N. E. J. Med.*; Vol. 227; p. 985). All of them responded fairly well, but not satisfactorily to injections of epinephrine. Four of them received one intramuscular injection of ETHER-IN-OIL; the remaining two received 2 each. *Within two hours, the asthmatic symptoms were rapidly controlled.* The patients became quieter, were able to breathe more easily and expectorate more freely. Thereafter, the usual palliative medications effectively controlled the symptoms.



ETHER-IN-OIL (Brewer) is recommended in addition to (or in conjunction with) Brewer's LUASMIN capsules and enteric-coated tablets—oral medication representing timed therapy in the symptomatic control of Bronchial Asthma.

For Rapid Clinical Improvement

. . . IN SECONDARY ANEMIA

PROMPT correction of hypochromic anemia is achieved with Neo-Ferinex. The formula presents: Iron in the bivalent form as ferrous sulfate, for highest availability, the important B complex vitamins, and Liver Concentrate, *in order to create optimal conditions* for iron absorption and utilization.

When administered in the recommended dosage of two capsules t.i.d., Neo-Ferinex supplies 12 grains of ferrous sulfate, an abundant supply of B complex vitamins which, together with those contained in the diet, provide an optimal daily allowance, and a significant amount of liver concentrate.

Neo-Ferinex is rapidly effective whether anemia is due to blood loss, infections, or iron starvation. Available in bottles of 100 and 500 capsules.

Each capsule contains:

Exsiccated Ferrous Sulfate	2 gr.
Liver Concentrate 1-20	3 gr.
Thiamine Hydrochloride	0.333 mg.
Riboflavin	0.333 mg.
Pyridoxine Hydrochloride	0.050 mg.
Calcium Pantothenate	0.175 mg.
Niacinamide	3.300 mg.

Plus other factors of the B complex as they occur in liver concentrate.

THE ANTIANEMIC FREE FROM GASTRIC REACTIONS

39% INCREASE DURING PAST YEAR IN PRESCRIPTIONS FOR

SPENCER SUPPORTS

To Aid Treatment of

LOW-BACK PAIN

Spencer Spinal Support designed for this woman to provide rigid support.

An ever-increasing number of doctors are discovering the efficiency of Spencer Supports designed individually for patients with low - back pain.

This is because each Spencer Support is especially designed for the patient to attain the specific result the doctor desires.

When Doctor Desires to Inhibit Movement of a Part

a Spencer is created to immobilize the part—and also improve posture. Therein lies the value of *individually designed* supports as compared to ordinary supports.

The degree of firmness in any Spencer Support is governed by the doctor. When rigid support is desired, rigidity is provided. Spencer Supports to provide rigidity are often used instead of a brace because they efficiently accomplish the purpose and *provide comfort* and *satisfaction* to the patient.

Spencer Supports are never sold in stores. For a Spencer Specialist, look in telephone book under Spencer corsetiere or write direct to us.

ПОДАРОК АМЕРИКАНСКОГО НАРОДА ЧЕРЕЗ АМЕРИКАНСКИЙ КРАСНЫЙ КРЕСТ

Gift of the American People Through the American Red Cross

"Certainly the place . . . to attack the metabolism of bacterial growth . . . is in the locality where that growth occurs." *

*Fenton, Ralph A.:
"Local Use of Sulfathiazole
in Otolaryngologic Practice",
Arch. Otolaryng., 37:491, 1943.

Local Chemotherapy with

White's

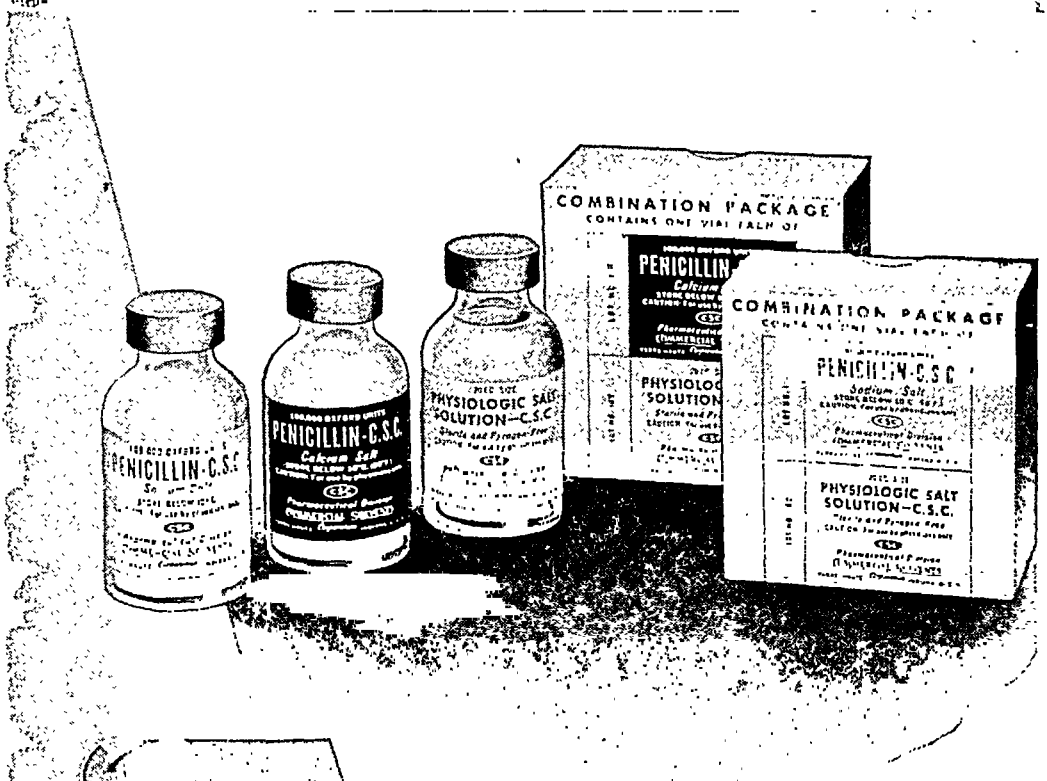
SULFATHIAZOLE GUM

Chewing even a single tablet provides a high, *sustained* salivary concentration of *locally active* sulfathiazole, averaging 70 mg. per cent over a full hour's chewing. Yet *blood levels* produced by even maximal dosage—and even in children—are for the most part too low to be quantitatively measurable. More effective *local* chemotherapy is thus made possible, while *systemic* toxic reactions are virtually obviated.

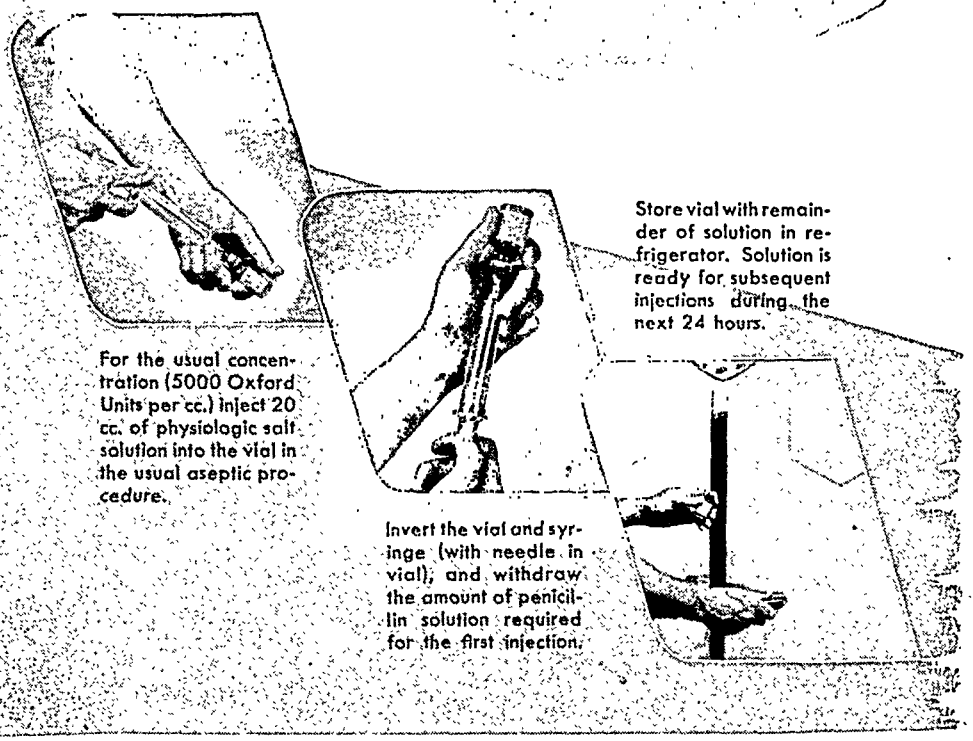
INDICATIONS: Septic sore throat, acute and chronic tonsillitis, pharyngitis, infectious gingivitis and stomatitis, non-epidemic infectious parotitis, peritonsillitis—caused by sulfonamide-susceptible micro-organisms. Preliminary studies indicate that Vincent's disease heals within 48-72 hours following start of treatment.

DOSAGE: One or two tablets of White's Sulfathiazole Gum chewed *for one-half to one hour* at intervals of one to four hours, depending on severity of condition. Should patients (children, for instance) find difficulty in chewing a single tablet for one-half to one hour, as many tablets as desired may be successively chewed during the period.

Available



IN PACKAGES OF 24 TABLETS, SANITAPED IN SLIP-SLEEVE PRESCRIPTION BOXES



—ON PRESCRIPTION ONLY.

A product of *White Laboratories, Inc.*

Pharmaceutical Manufacturers, NEWARK 7, N. J.

The Combination Packages of

For the usual concentration (5000 Oxford Units per cc.) inject 20 cc. of physiologic salt solution into the vial in the usual aseptic procedure.

Invert the vial and syringe (with needle in vial), and withdraw the amount of penicillin solution required for the first injection.

Store vial with remainder of solution in refrigerator. Solution is ready for subsequent injections during the next 24 hours.

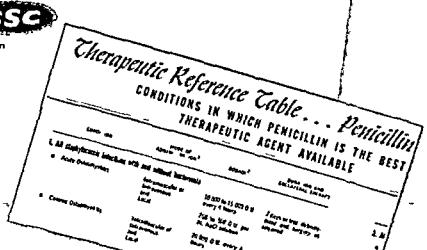
PENICILLIN-C.S.C.

For administration in the physician's office or in the patient's home, Penicillin-C.S.C. will be available in a convenient combination package, as soon as the drug is released for unrestricted use in civilian practice. This combination package provides two rubber-stoppered, serum-type vials. One vial contains enough physiologic salt solution to permit the withdrawal of 20 cubic centimeters The other vial contains 100,000 Oxford Units of penicillin sodium or penicillin calcium* respectively.

The physiologic salt solution is sterile and free from fever-producing pyrogens. Penicillin-C.S C — whether the sodium salt or the calcium salt—is bacteriologically and biologically assayed to be of stated potency, sterile, and free from all toxic substances, including pyrogens, as attested by the control number on the package.

When 20 cc. of the physiologic salt solution is withdrawn from its vial, and injected into the penicillin-containing vial under the usual aseptic precautions, the resultant solution presents a concentration of 5000 Oxford Units per cubic centimeter. The solution is then ready for injection, does not require resterilization.

After the desired amount of the solution for the first injection has been withdrawn, the vial containing the remainder of the solution should be stored in the refrigerator. It is ready for the next injection—the desired amount then merely has to be withdrawn under proper sterile technic.



When released for unrestricted marketing, Penicillin-C.S.C. will be stocked throughout the United States by a large number of selected wholesalers Any pharmacist thus will be able to fill professional orders promptly.

THE BIBLIOGRAPHY SPECIFIES ERTRON*

In the Treatment of Arthritis

A wealth of published evidence furnishes the background for your use of ERTRON in the treatment of arthritis.

Ten years of comprehensive research into the various phases of ERTRON therapy in leading institutions throughout the country has produced an extensive bibliography on the safety and effectiveness of ERTRON in arthritis.

The results published by the investigators do not apply to any product other than ERTRON—the product employed in the clinical studies.

Usual therapeutic responses to ERTRON include one or more of the following: reduction of pain, diminution of soft tissue swelling, increased range of motion and exceptional restoration of normal function.

ERTRON alone—and no other product—contains electrically activated, vaporized ergosterol (Whittier Process).

NUTRITION RESEARCH LABORATORIES • CHICAGO

It fights infection while she sleeps

The striking success of Paredrine-Sulfathiazole Suspension in nasal and sinus infections is largely due to its prolonged bacteriostatic action. When the Suspension is administered on retiring, for example, sulfathiazole can often be observed on infected mucosa the next morning—conclusive evidence that bacteriostasis has persisted all night long.

The fundamental reason for this prolonged bacteriostatic action is the fact that Paredrine-Sulfathiazole Suspension—not a solution, but *a suspension* of free sulfathiazole—covers the nasal mucosa with a fine, even frosting of sulfathiazole, which does not quickly wash away. Yet the Suspension does not cake or clump, and does not interfere with normal ciliary action.

Other outstanding advantages:

1. The Suspension does not irritate or sting, because its pH is slightly acid, and identical with that of normal nasal secretions.

2. The Suspension does not produce such central nervous side effects as insomnia, restlessness and nervousness.

Smith, Kline & French Laboratories, Philadelphia, Pa.

PAREDRINE-SULFATHIAZOLE SUSPENSION

1 *Prolonged* bacteriostasis

2 *Non-stimulating* vasoconstriction

3 *Therapeutic* pH—5.5 to 6.5

HORLICK'S AND THE DISCHARGED PATIENT

When the patient is discharged from the hospital, every effort is used to encourage his continuing good dietary habits.

To provide the incentive for the patient to persevere in the intake of a highly nutritious diet, an acceptable supplemental food should be advised.

HORLICK'S

is a well-balanced food, supplying biologically complete protein in addition to easily utilizable, partially predigested carbohydrate. Because it is so quickly digestible, Horlick's does not interfere with the next full meal. It is delicious whether prepared with milk or water.

IRON-DEFICIENCY ANEMIA

The blood in iron-deficiency anemia is markedly benefited by Copperin administration: hemoglobin percentages quickly rise; red blood cells increase in quantity and improve in quality.

Due to the action of the catalyst, copper sulphate, the amount of iron ammonium citrate per capsule is reduced to only 32 Mgm. But as ALL the iron is made available, maximum therapeutic effect is obtained. Copperin does not stain teeth or irritate the gastrointestinal tract and is water soluble. Prescribe Copperin "A" for adults, Copperin "B" for children.

WARMTH

Imadyl Unction brings relief to painful areas—to nerves, joints, and muscles—through the warmth of improved circulation. Its two chief ingredients, histamine and acetyl-glycol-salicylic ester 'Roche', incorporated in a highly absorbable base, readily penetrate the skin. Use Imadyl Unction as an adjuvant to general treatment, in neuritis, arthritis, and other rheumatic diseases. Apply locally, to the pre-heated skin of the painful area.

HOFFMANN-LA ROCHE, INC., NUTLEY, N. J.

WELCOME WARMTH THROUGH IMADYL UNCTION

Because of ARGYROL'S decongestive, bacteriostatic, stimulating action, marked relief in head colds usually follows treatment with ARGYROL These approaches to three foci of the common cold are suggested

1 To the nasal meatus . . by 20 per cent ARGYROL instillations through the naso lacrimal duct
2. To the nasal cavities . . with 10 per cent solution of ARGYROL in drops or by ARGYROL tamponage
3 To the fauces and pharynx by swabbing with 20 per cent ARGYROL solution

HOW ARGYROL ACTS

DECONGESTIVE—ARGYROL'S decongestive effect in the membrane is the result of its demulcent, osmotic action The withdrawal of ARGYROL tampons from the post nasal cavities frequently brings forth a long ropy mucous discharge measuring as much as two feet or more.

BACTERIOSTATIC—Although proved to be definitely bacteriostatic, ARGYROL is non toxic to tissue In nearly a half century of wide medical use of ARGYROL, no case of toxicity, irritation, injury to cilia or pulmonary complication in human beings has ever been reported

STIMULATING—Soothing to nerve ends in the membrane and stimulating to glands, ARGYROL S action is more than surface action For it acts *synergetically* with the membrane's own tissue defense mechanism

When you order or prescribe ARGYROL, make sure you specify Original Package ARGYROL

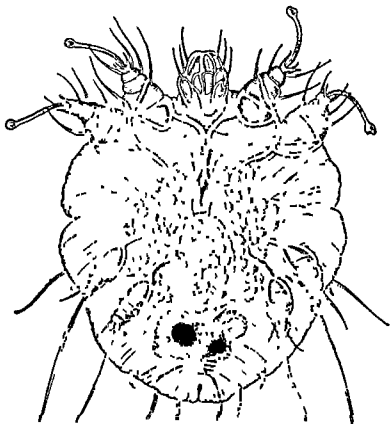
BELBARB

AN *Excellent* SEDATIVE *and* HYPNOTIC



The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg, Arch. f. exp. P. & P. CLX, 276) renders possible attainment of desired effects with relatively small doses, thus avoiding "hang over" and other unpleasant side-actions. In contrast to galenical preparations of belladonna, such as the tincture, Belbarb *has always the same proportion of the alkaloids.*

Indications: Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

Formula: Each tablet contains ¼ grain phenobarbital and the three chief alkaloids, equivalent approximately to 8 minims of tincture of belladonna.

Belbarb No. 2 has the same alkaloidal content but ½ grain phenobarbital per tablet.

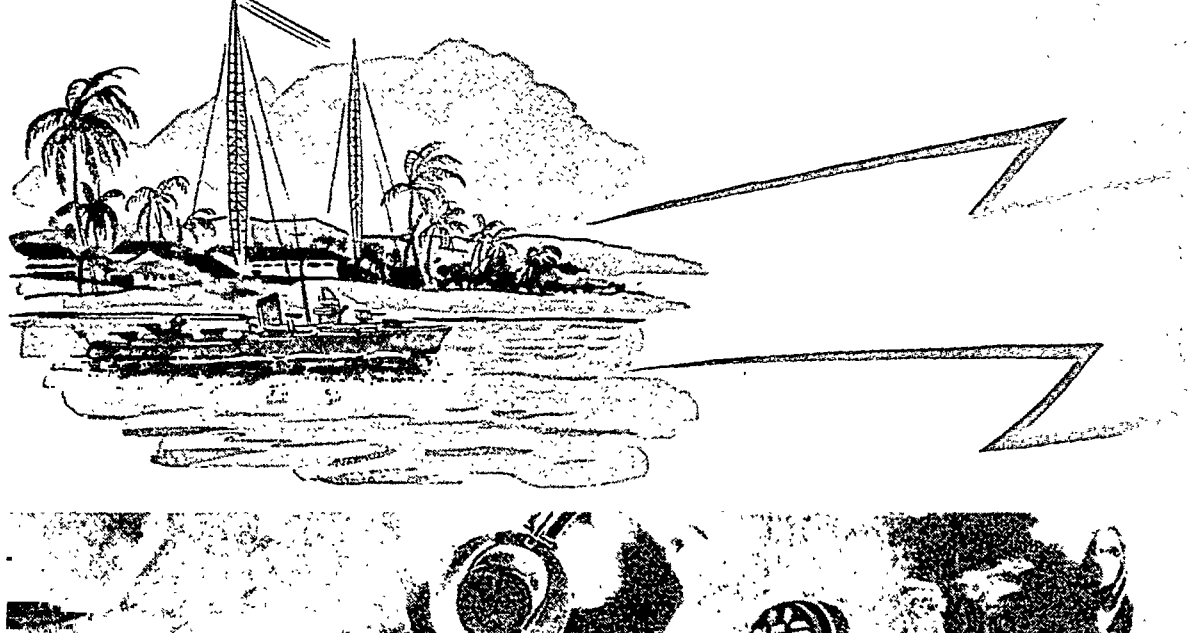
CHARLES C. HASKELL & CO., INC., RICHMOND, VIRGINIA

A NEW *effective* treatment for Scabies

No longer are slow, greasy ointments with their attendant messiness necessary to treat scabies. In their stead has come quick, easily applied, highly parasiticidal benzyl benzoate emulsion. • • • Writes Mackenzie[1]: "The ease and speed with which the application can be carried out...rapidity of cure, and the almost immediate relief from itching combine to make it a satisfactory remedy from both the clinical and the public health aspects."

'WELLCOME' **BENZYL BENZOATE** EMULSION 50%

Application: Following a thorough soap and water bath, the emulsion (diluted to 25%) is painted on the entire body, allowed to dry, and then reapplied. A warm bath, 24 hours later, completes the treatment



Bottles of 4 fl. oz. and ½ gal.

The details of this dramatic story were reported in daily newspapers on December 6, 1944—a tribute to the skill and ingenuity of the physicians in our Armed Forces.

RÂLES by RADIO

"Your man has an asthmatic attack . . . wrap him in blankets with hot water bottles and give him an injection of Adrenalin Chloride"

Spanning hundreds of miles of ocean, these life-saving directions of a Navy doctor in Hawaii were carried by radio to a small vessel "somewhere in the Pacific" on which a seaman lay unconscious. A stethoscope over the patient's chest with ear pieces pressed close to the microphone had made it possible for the physician to hear the breath sounds and heartbeat in Honolulu.

Thus in war, as in peace, Adrenalin Chloride is the first thought of the physician for the prompt relief of asthmatic paroxysms.

Its ability to relax spasms of bronchial musculature, to stimulate the heart with increase in cardiac output, to raise systolic arterial pressure and widen pulse pressure, and to constrict blood vessels of the skin gives Adrenalin a dynamic and diversified therapeutic action.

In addition to its use in bronchial asthma, Adrenalin (epinephrine) is widely employed as a hemostatic, as a vasoconstrictor in vascular engorgement of the nasal passages, to prolong the effect of local anesthetics, and as an aid to resuscitation in shock and anesthesia accidents.

PENICILLIN CANNOT BE MADE IN A CRUCIBLE!

Bring back Paracelsus and his crucibles today...show him the clinical picture of Penicillin...take him on a trip through a great Penicillin plant like that of Cheplin Laboratories. What would he think? Your guess is as good as ours!

Just as strides in clinical medicine have been unmeasurable since Paracelsus' time, so too have been the strides in mass-manufacture and plant-investment. In the Cheplin plant at Syracuse, for instance, there are alone thirty miles of pipe needed to make this new "wonder-drug."

Who can state Medicine and the Pharmaceutical Manufacturer aren't working together for a better post-war world? And Cheplin is doing its bit!

For the symptomatic relief of sinusitis

In relieving the discomfort which almost invariably accompanies acute sinusitis, the striking success of Benzedrine Inhaler, N.N.R., is as logical as it is gratifying:—

The Inhaler's vasoconstrictive vapor diffuses evenly throughout the upper respiratory tract, opening sinal ostia and ducts which are frequently inaccessible to liquid vasoconstrictors. The sinuses drain. Headache, pressure pain, "stuffiness" and other unpleasant sinusitis symptoms are relieved.

A Better Means of Nasal Medication

Benzedrine Inhaler

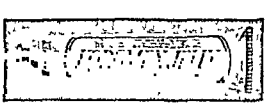
recent extensive investigation confirms contraceptive effectiveness of the active ingredient in Koromex Jelly

A most illuminating report based on extensive clinical and experimental data has recently been published by Eastman and Scott (Human Fertility, 9:33, (June) 1944.) *These authors studied the safety* and efficacy of phenylmercuric acetate which is the active constituent of Koromex Jelly.

1 Clinical evidence showed that in actual use, phenylmercuric acetate jelly had a remarkable record for contraceptive efficiency.

2 The earlier work of Baker, Ranson and Tynen (Lancet, 2:882, (October 15), 1938), showing a very high spermicidal potency, was confirmed.

3 Toxicity was found low.



4 No evidence of irritability on the part of either the husband or wife.

In addition to the above qualities, Koromex Jelly, which also contains oxyquinoline benzoate and boric acid in a well buffered glycerine gum base, has the properties of adhering firmly to the vaginal lining and mixing readily with the vaginal secretions. It has optimum spreading qualities. Its pH of 4.6 is constantly maintained even in the presence of the buffering action of the protein seminal fluid.

Koromex Jelly does not stain. It is not excessively lubricating, and is well tolerated. Because of these qualities you can assuredly — prescribe Koromex *with confidence.*

Reaches and Destroys the Pathogens in Throat Inflammation

CĒPACOL

Brand of Alkaline Germicidal Solution

Cēpacol is rapidly effective against pathogenic bacteria associated with sore throat, and at the same time, acts as a mildly alkaline cleansing solution that allays irritation and soothes inflamed tissues.

Due to unusually low surface tension, recesses of the mucosa are reached by Cēpacol and cleansed by its foaming detergent action. In clinical use it is nontoxic, nonirritating, nonastringent, and does not interfere with healing.

Cēpacol can be used as spray or gargle, full strength or diluted with an equal volume of water. Its delightful, refreshing flavor invites cooperation by the patient.

At prescription pharmacies in pints and gallons

Indicated therapy in Sequelae of

Epidemic Encephalitis

Pills Stramonium (*Davies, Rose*)

2½ grains

Physicians in private practice as well as in neurological clinics have widely prescribed these pills since 1929, and their continued interest in and use of them points to the serviceability of this therapy.

Stramonium Pills (*Davies, Rose*) exhibit in each pill 2½ grains of alkaloidally standardized Stramonium (powdered dried leaf and flowering top of Datura Stramonium, U.S.P.), equivalent to 25 minims (1.54 cc.) of Tincture U.S.P.

As a reassurance of the activity of the finished pills, they, too, are alkaloidally assayed, thus establishing as far as possible uniformity and dependability.

A package for clinical trial and literature mailed free of charge upon request.

Peptic Ulcer treatment with Phosphaljel

PHOSPHALJEL possesses antacid, astringent and demulcent properties analogous to those of aluminum hydroxide gel.

PHOSPHALJEL was used experimentally in the first successful attempt to prevent post-operative jejunal ulcer in Mann-Williamson dogs. It was found possible by the use of Phosphaljel to prevent such ulcers in 20 of 23 animals. In a group of animals allowed to develop Mann-Williamson ulcers, the administration of Phosphaljel caused complete healing of the ulcers in 9 of 10 animals. These results were described as "the best we have obtained with any therapy" (1).

These striking experimental results led to the use of Phosphaljel in the treatment of peptic ulcer in man (1,2,3,4,5) and disclosed its special value in those cases of peptic ulcer associated with a relative or absolute deficiency of pancreatic juice, diarrhea, or low phosphorus diet (1).

Editorial

Nurses for the Armed Forces, II

More nurses are needed for the armed forces. On that point there seems to be general agreement.

How many are needed? In the January, 1945 issue of the *New York State Nurse*[1] we find these statements: "On my return from England and France, I found that the Army had made a nation-wide plea for 10,000 *more* nurses at once . . . ." in a letter signed Frances Payne Bolton, Committee on Foreign Affairs of the House of Representatives; also "The Army Nurse Corps must have 10,000 nurses in the shortest possible time," reprinted from an editorial in the *American Journal of Nursing* for November, 1944. In the New York *Times* report[2] of a special meeting at Hotel Pierre, New York, Maj. Gen. Norman T. Kirk, Surgeon General of the Army, is quoted as calling for 10,000 *additional* nurses. Rear Admiral Reed, at the same meeting, is quoted as having said "by June 30 we will need 4,000 *more* nurses" for the Navy.

How many nurses are *now* available? As of October, 1944, Major General Kirk is authority for the statement:[2] "We sent a personal appeal to each one of the 27,000 nurses that the War Manpower Commission told us were available for duty. . . . We received 760 answers and signed up 227 nurses from that group."

On the radio, January 6, 1945, and in his message to the Congress President Roosevelt called for the drafting of nurses for the armed forces, stating:

"Last April the Army requirement for nurses was set at 50,000. Actual strength was then 40,000. Since that time the Army has tried to raise the additional 10,000. Active recruiting has been carried on, but the net gain in eight months has been only 2,000. There are now 42,000 nurses in the Army.*

"Two hundred eighty thousand nurses are now practicing in this country. It has been estimated by the War Manpower Commission that 27,000 *additional* nurses could be made available to the armed forces without interfering too seriously with the needs of the civilian population for nurses."

What, then, may the need be by March or June?

Now it is our impression that the Surgeons General have been somewhat less than frank with respect to the needs of the armed forces and the failure of the recruiting program and the requirements of other government services for nurses. Reasons of security have possibly governed the release of figures on expected casualty lists. Yet it would be absurd to infer that within reasonable limits the expectancy of casualties and therefore the need for nurses has not been calculated in advance. That is elementary staff work. It should be possible for the Surgeons General to state approximately the need for nurses for each year of the war.

How otherwise are preparations to be made to meet the requirements? It seems absurd, as reported in the *Herald Tribune* under the dateline Washington, D.C., December 27, that "Eleven Army hospital units are being sent overseas without any nurses," this being the statement of Basil O'Connor, chairman of the American Red Cross.

No one states whether these units were to pick up their nursing complements overseas or not, but it is *implied* that there were not enough nurses to fill the requisitions and it *is* stated that "this is an unprecedented event in this war."

We are not attempting to minimize the seriousness of the nursing shortage, merely to clarify it. Any doctor or civilian hospital director knows from personal experience how curtailed the civilian situation is. But, on December 12, 1944, in the New York *Herald Tribune*, Dorothy Dunbar Bromley, quoting Miss Dorothy Wheeler, director of the New York City Nursing Council for War Service, accuses the doctors by inference and direct statement for their failure to ration nurses. In general, it is the patients who hire the nurses, frequently without bothering to consult the physician. In the hospital, floor-duty nurses are assigned by the administration, and private-duty nurses are obtained through the hospital registry or by the nursing office through a nurses' registry.

What is the present status of Army and Navy casualties?

Are they in fact, or are they not receiving good care? Until now we have been led to believe that the care has been excellent, and this from official sources. How can it be good and poor at the same time?

What is the present status of nursing services in the civilian hospitals? How does it compare as to age of nurses, number, and *quality*, with 1940 or 1941? Has the American Hospital Association or any other authoritative body made such a survey? It is useless to single out specific hospitals for censure, as was done by Major General Kirk[2] in the case of "one civilian hospital in New York City (which) has 743 patients and 826 nurses on its staff." We want to know and are entitled to be informed of what the over-all picture is in *all* the hospitals of the country. Fourteen years ago, 55 per cent of our nursing profession were conducting individual private practice according to the Committee on the Costs of Medical Care. The National Nursing Council for War Service says that in 1944, the 60,499 private-duty nurses are only 16 per cent of the 385,182 total of all nurses. This will drop to 55,000 two years hence in the opinion of the Council. Thus, if estimates are correct, only one graduate nurse in eight will be in private practice.

What is wrong with the recruiting service for nurses which admits of 27,000 nurses available and has not been able to recruit but a "pitifully inadequate" number, again in the words of Maj. Gen. Norman T. Kirk?[2] It is unthinkable that there is that number of unpatriotic nurses, but it is quite thinkable that red tape and confusion in recruiting methods could account for at least some of the poor response. This is so stated in Miss Bromley's article in the *Herald Tribune* for December 31, 1944. It is hard to see how the nursing and medical professions could be blamed for this!

We are informed that there are about 105,000 Cadet Nurses in training, that 1,200 already have been graduated, and that 25,000 more will be graduated in 1945. What has happened to the 1,200 graduates of 1944, and what will happen to the 25,000 graduates of 1945? The contract[3] which each such Cadet Nurse signs with the Federal Security Agency states "In consideration of the training, payments, and other benefits which will be provided me

if I am accepted as a member of the U.S. Cadet Nurse Corps, I agree that, if accepted, I will be available for *military*** or other Federal governmental or essential civilian services for the duration of the present war." Signatures of applicant and parent or legal guardian are required.

Yet the *Fact Sheet*[4] of the U.S. Cadet Nurse Corps, a bulletin of information for recruits, states, under the heading of "Answers to Questions Most Frequently Asked," "In return for advantages received through the Corps, *Cadet Nurses promise* that, health permitting, they will remain in essential nursing for the duration of the war. The choice of *which** essential service is theirs. They are *not required to pledge themselves* to military service." For this, we are informed, the government is disbursing $60,000,000 yearly. We wonder, and could blame no Cadet Nurse or her parent for being confused as to what her obligations for military service are. The *Fact Sheet* seems to be quite definite that she has none.

We can readily understand the confusion and consequent lack of results in the nurse procurement program.

Adequate Diet, II

For nearly a century the question of the optimum protein in the diet has been debated by scientists and laymen alike. Physicians have had their voice in the matter also, particularly on the possible effect of protein on the kidney. One does not have to go back in the literature more than two decades before finding recommendations for restricted protein diets for patients having protein loss in the urine. Fortunately, modern research has partially clarified many points in the former controversy and has rendered untenable the old ideas held by many that high intakes of protein are physiologically harmful.

Attention is now focused on the question of the minimum nutritional need for protein, for now such physiologic and pathologic problems[1] as growth, immunity, blood formation, wound healing, pregnancy, lactation, bone formation, edema, and liver diseases are known to be related to the amount and quality of protein in the diet. The specific need of protein nutrition is for the amino acids of which proteins are made, and different proteins—and thus different foods—vary in their content of the acids which are essential. While it was formerly thought that protein in itself was required to control many of these physiologic and pathologic effects, considerable evidence has accumulated[2] that other constituents of protein foods, namely, minerals and vitamins, may account at least in part for many of them. Re-evaluation of protein's role has been stimulated by wartime needs for clarification, hence a considerable number of studies are being made at the present time. Knowledge of the dependency on protein in the diet for wound healing[3] and blood formation[4,5] is a contribution of considerable clinical importance at this time.

It should be kept in mind that protein foods and proteins are not synonymous. A high-protein diet means high-protein foods which have, in addition to protein, other important nutrients such as minerals, vitamins of the B complex, fatty acids, and fat-soluble vitamins. There is general agreement that the present recommended dietary allowances[6] for protein are fully adequate as applied to the usual mixed diets and are probably more generous than necessary with certain food combinations.

When a physician prescribes certain protein foods which are superior in amino acid makeup, he is confronted with the problem of whether it is economically possible for his patient to follow the prescription. As in the case of fat, protein of animal origin is expensive to produce in comparison to protein of vegetable origin. Certainly animal protein is the preferred source from the point of view of patient's choice, for we Americans are among the economically fortunate peoples of the world who have

liberal intakes of animal protein ingrained in our eating habits. On the other hand, Eastern peoples have subsisted fairly well for centuries on diets containing less than 10 per cent of their protein from animal sources. It is quite likely that the food experts of the United Kingdom,[7] when following the policy in the war emergency of recommending that the supply of animal protein should not fall below 40 Gm. per day, or approximately one half of the total needed protein intake, had in mind consumer morale as well as physiologic requirements.

Our own Food and Nutrition Board of the National Research Council[8] has put itself on record as follows: "There are not sufficient data for stating categorically the minimum amount of protein per day which must come from biologically superior foods. The *variety* of protein consumed should be stressed, and sufficient 'animal protein' should be included to prevent monotony of the diet to the degree where it might decrease consumption and thus effect nutritional status." The idea that hard work steps up the protein need has been largely dissipated, even though beefsteaks remain the preferred food of the athlete and the manual laborer. Stare and Thorn[1] recently found that the amount of protein in the ordinary diet of an active adult may be safely reduced to 50 Gm. per day, of which as little as 5 Gm. may be in the form of animal proteins. However, because their volunteers were studied for a limited time (only eight weeks) further studies over longer periods are needed.

As in the previous discussion on fats, an attempt has been made here to point out that there are various vegetable and animal sources of protein upon which the human diet can draw. The physiologic requirements of the body appear to be better fulfilled when both sources are used. Meat, the more palatable source of protein, contributes palatability to the meal as a whole, thus helping to insure consumption of other less palatable foods which have nutritional importance.

It is evident from this review that protein plays an important role in many physiologic and pathologic processes; that the body can tolerate wide limits of intake without injury; that the specific requirement cannot be stated as exactly as in the case of calories, because the kind and source of protein is important; but that in a varied diet which is satisfactory in other respects, a minimum of 10 per cent of the calories should be protein for an adult, and 12–15 per cent for a growing child.

TO PRACTITIONERS OF MEDICINE

The nursing need for the armed forces is extremely acute. Will *you* help by observing the following suggestions?

1. Employ no nurse of military age, except when absolutely necessary.
2. Urge your patient to employ no unnecessary service, and use practical nurses when possible.
3. Explain to your patient that the use of a special nurse may deprive a wounded relative or friend in the armed services of vital nursing care.

THE PLACE OF THE MASS SURVEY IN THE TUBERCULOSIS CONTROL PROGRAM

H R Edwards, M D , F A C P , New York City

THE examination of apparently healthy individuals with no known history of exposure to tuberculosis dates back many years Until 1933, such studies were directed almost exclusively at the school child Since 1933, there has been an increasing emphasis placed on the detection of tuberculosis in the adult population, with the result that a much higher percentage of significant disease has been found Efforts in this direction attained their highest peak when the armed forces adopted the chest x-ray as a required part of the examination for all men and women entering the service The true significance of this type of program is now being felt and will become increasingly more important as such services are made available to a greater number of persons

The total number of individuals who have had a chest x-ray in this country during the past ten years as a means of discovering latent or active tuberculous lesions is unknown, but if one may judge from the numbers who have been cleared by the induction centers throughout the nation, the examinations made in industry, in public and private clinics, to say nothing of the chest x-ray examinations made by the practicing physician and roentgenologist, then the total number must run well into the millions

The mass survey program has been developed extensively in New York City by the Department of Health since 1933,[1] and, through 1943, over half a million individuals have been examined We have found approximately 2 per cent with evidence of chronic pulmonary tuberculosis, of which one-third of the cases are considered to be significant A report[2] on the eight years' service in district clinics of the Department of Health, as well as surveys between 1933 and 1940, indicated chest x-ray examinations of approximately 797,759 individuals, all for the purpose of detecting tuberculosis

In addition to these examinations, we should consider the men of draft age who have been examined at the induction centers since 1940 [3-5] A report by Colonel McDermott in the New York *Times* of March 5, 1944, indicated that 700,000 men in New York City had entered the armed forces Presumably, therefore, well over a million men were examined in this screening process The initial x-ray was made by the Army, except the work done in 1940 by the Department of Health, and, from the beginning, the Department of Health, in cooperation with the United States Army and the local Selective Service, has made a prompt re-examination of approximately 94 per cent of all men rejected on the basis of lesions seen in chest roentgenograms This work represents a tremendous saving in original survey cost to the Department, and at the same time brings to our attention the significant lesions in need of follow-up

Two of the Tuberculosis and Health Associations in New York City have made considerable contribution to this work During the period of 1933 to 1943, the Queensboro Tuberculosis and Health Association examined by chest x-ray in their consultation and survey services approximately 110,860 individuals In earlier years, their services were devoted entirely to school children Efforts in the industrial field started in 1938, when 162 examinations were made, and the number markedly increased to a total of 12,264 in 1943 Over 60 per cent of their services have been rendered since 1939 The Brooklyn Tuberculosis and Health Association during the period from 1933 to 1943 examined 27,610 persons in surveys They also x-rayed 58,681 pupils under 15 years of age in public schools, not as a case-finding venture but as a health education project with the Department of Education

To these rather impressive totals should be added many more thousands of individuals who have had chest x-rays in the various chest clinics and other outpatient services connected with hospitals and by physicians in New York City Although the exact figures for all of these services are impossible to compute, it may be conservatively estimated that for the period 1933 to 1943 approximately 2,500,000 individuals in New York City had a chest x ray for the purpose of detecting previously undiscovered tuberculosis

Considering our surveys as a whole, approximately 2 per cent of those examined revealed lesions characteristic of chronic pulmonary tuberculosis, of which about one-third are classified as of some clinical significance—that is to say, they are either open infectious lesions or the x-ray shadows are of such a nature that a definite opinion cannot be reached without periodic supervision to determine the stability of the lesion Approximately half of these so-called significant lesions will eventually be classified as

Director Bureau of Tuberculosis New York City Department of Health.

arrested. Reports of other workers who have done mass surveys are quite similar to ours in the ratio of significant to arrested lesions. They vary from one to two significant cases for each one classified as arrested.

Our program here in New York City has been developed with a clear-cut policy from the beginning. The first objective has been to demonstrate the need and the relative significance in certain population groups as productive sources of case-finding. This is important on the basis of sound business administration, so that each dollar invested will yield the maximum results. To this end, we extended our surveys to a wide variety of age, racial, and economic classes of the population. Our findings have been published,[1] and may in general terms be summarized as follows.

Significant tuberculosis is most prevalent in the adult population, usually in persons 20 years old or older. From the standpoint of race, the colored population is of extreme importance, because it is among the nonwhite that we have the highest mortality rates. While the prevalence of tuberculosis among white and colored of all ages in mass surveys reveals higher rates for the white, the age factor between the two groups reveals a very significant difference. Dividing them at 25 years, we consistently find higher rates among the colored below that age than we do in the white population. Also, we find more significant lesions among the colored than among the white, with more evidence of healed lesions in the white than in the colored.

The second objective of our program has been to demonstrate an effective method of doing the job. In general, this may be divided into three stages: surveying, review and classification, and, finally, the permanent supervision of the case found.

In the survey phase of the program, we have used the rapid roll-paper method in all of our surveys, and in only a few involving school ages have we utilized the tuberculin test as a pre-screening method. The roll-paper method has proved very satisfactory to us, because primarily the diagnostic quality of the lesion is, in our opinion, superior to other available methods for mass work.

Second, it has been used on a service basis, which means that we could use a single unit or several units at the same time without the administrative difficulty of owning and staffing one or more units that are seldom used consistently day in and day out. It is our feeling that the net monetary saving in operating surveys in this manner has been greater than if we had made a capital investment in equipment and carried the staff necessary for its operation.

We believe that the tuberculin test should have a part in the mass survey program when pupils in schools are considered. Preselection by this test results in a definite saving in x-ray service. It does, however, add an extra step in the survey program, as the students must make at least two visits, one to receive the test, and a second for its reading, at which time those positive may be x-rayed. In our experience the school authorities object to the tuberculin test for the above reasons, and, unfortunately, many have a fear of severe reactions to the test, which of course has little basis in fact. We advocate the use of tuberculin in school populations primarily from the standpoint of economy, rather than as an epidemiologic index to the prevalence of infection, although it should be pointed out that such indices based on careful tuberculin testing surveys are of the greatest value in evaluating the tuberculosis program in a given community. This becomes quite obvious when one considers findings such as the following. In a recent patch-test survey in the borough of Queens, 10 per cent of approximately 30,000 school children proved to be reactors. A similar survey in the Central Harlem District, chiefly among a colored population of high-school age, revealed approximately 40 per cent reactors. Therefore the prevalence of infection is a good indication of where the most tuberculous disease may be found.

We believe the patch test to be very satisfactory for this type of screening operation. It has the advantage that it may be easily done by a nurse or a trained technician, whereas the intradermal test (Mantoux) seems to be more properly the responsibility of the physician. In our work, the physician reads all tuberculin tests and administers the Mantoux test when it is used. Since the purpose of the test is that of a rough screening device to conserve x-rays, there would seem to be no logical reason why either the patch or Mantoux test may not be administered and read by a trained technician.

Time will not permit a detailed discussion of the use of survey forms, clerical staff, and organizational details incident to the efficient conduct of the complete survey phase of the mass case-finding program, although it should be remembered that they do constitute a major part of the job.

Review and Classification

For purposes of rapid and complete analysis of the findings of mass surveys, all x-ray pictures have been read centrally, and for those patients needing further examinations, including physical, x-ray, fluoroscopy, sputum, etc., these have been completed at the same point. Our district organization of clinics is composed of twenty-two

such units; therefore it would obviously be difficult in large-scale mass surveys to compile our results based on the findings in a number of district units. There is also the problem of a lack of uniformity that would result if such work were done by a central staff. The central clinic of the Department is easily accessible by all transportation facilities in the city and has offered other time-saving devices in our work. The classification of cases by us on the basis of the survey examination, with a complete examination following, gives the Department the needed information about the significance of a given case. If the physician received only an interpretation of a survey film, we would never be quite sure that the significance of the x-ray shadow would be fully appreciated by him.

There are still too many physicians who evaluate tuberculosis on the basis of the common clinical symptoms and physical findings, and there are too many who base a diagnosis upon a positive sputum before considering a lesion as significant, if tuberculous at all.

More recently, we have developed the idea of localized mass surveys in connection with our district clinics. This has been possible through the installation of a new x-ray device,[6] using roll paper.

This unit can be used with the standard x-ray equipment in each clinic, and it is estimated that it can increase by 50 per cent the number of films which can be taken by the staffs in our local clinics. If this development is used to its maximum in all clinics, it is estimated that an additional 200,000 persons will be x-rayed each year. This goal will probably not be attained immediately, owing to the curtailment of staff on account of the war effort.

The operation of mass surveys, involving 200 or more examinations per day, is difficult as a day-by-day program, unless one is working in a controlled population group, such as a school, an induction station, an industry, or the like, where large numbers of persons are easily available. Miller and Henderson[7] have reported on a survey conducted under this plan which utilized the resources of the Department of Health and the Department of Welfare in New York City, and which effectively reached over 3,500 persons on Home Relief. Similar programs will be developed in this new plan in the various clinic districts, with the Department of Welfare and other agencies having access to or control of potentially significant population groups in so far as undiscovered tuberculosis is concerned. In these localized studies, the survey film is read and such follow-up as is indicated is done by the district clinic staff rather than at the central clinic, as in the case of large-scale mass surveys.

Permanent Supervision

There is no excuse for conducting mass surveys unless there are adequate facilities for the proper follow-up of cases found, and for the examination of the contacts. This has been an inflexible policy in our program from the beginning of our mass surveys in 1933. The subsequent supervision of cases found may be divided between those who go to their physicians and those who have no physician and usually cannot afford one and therefore go to a district clinic.

From the standpoint of the physician, the mass survey program has brought to his attention thousands of cases that he would not have seen otherwise. This is also true of the radiologist. It is reasonable to suppose that these individuals would not have sought medical advice until symptoms had appeared. All too frequently the general practitioner does not refer patients for chest x-ray unless they have reasonably clear-cut symptoms, and even then he may hesitate because of the expense involved. Undoubtedly there are scores of patients with indefinite symptoms who should have a chest x-ray as part of their routine physical examination in the proper evaluation of their medical problem.

Our surveys among applicants for employment in the Fire Department and the Department of Education in New York City may be cited as evidence that the survey does place cases under the care of physicians. Since 1937, we have x-rayed the chests of several thousands of such applicants, and we have found, on the average, that 1 per cent are in need of further supervision. It has happened rarely, if at all, that the individual has not immediately sought the advice of his physician, and in some instances he has gone to several physicians for additional consultation. In all of our surveys, literally thousands of individuals have been referred to their physicians for subsequent care. Thus far the Department has had no difficulty in coming to a mutual understanding with the physician regarding our findings and recommendations in these cases, although, of course, not all physicians will follow the recommendations made by the Department. The Department of Health is anxious to assist and cooperate with the physician in these problems, and for this reason we have, since 1920, operated free consultation services for the physician caring for a patient with definite or suspicious symptoms, and yet who is unable to pay standard fees for a chest consultation.

Those individuals not under the care of a physician become immediately a problem for the district clinic, where they receive the same supervision which is provided for a patient and his contacts in any district clinic service.

If the patient discovered in a survey wishes to return to his physician, then after a proper classification of his disease has been made in the central or district clinic, a report is sent to the physician indicating our findings and recommendations. These reports are sent only when requested by the physician, because it has been found that the patient may not go to the physician as he has promised. In all such instances, the case is registered in the same way as any other new case discovered in the city in the district of his residence. Thus if the physician does not assume the responsibility, or if the patient fails to go to his physician for supervision, our district nurse will make a visit to the home and make arrangements for necessary supervision, whether that be under a private doctor or a district clinic.

The third objective of our program has been to stimulate the interest of groups such as industry, schools, labor organizations, and others having an interest in a given population, to assume the responsibility for repeated surveys.

A survey at a given time reveals only the amount of disease that has developed at that time. Thus in the ultimate plan to eradicate tuberculosis, it is necessary to repeat mass surveys in a given population at intervals to detect any new disease which may have developed in the interim. The splendid work of Fellows[8] in the Metropolitan Life Insurance Company, Sawyer,[9] of the General Electric Corporation, and others has clearly indicated the importance of periodic examination in controlling tuberculosis among their employees.

It must be remembered that as the surveys are repeated in a given population each subsequent examination is likely to reveal a lower prevalence of the disease than the previous examination, but also to reveal that the new lesion found is more likely to be of some significance, because of its more recent development.

It has not been our feeling that the Department of Health should assume the permanent administrative control of mass surveys, nor that it is necessarily a responsibility of government to operate indefinitely such services at public expense. If the mass survey is a logical and valuable weapon in disease prevention, which we believe it to be, then those agencies or organizations able to pay for such service should assume as much of that responsibility as possible. In other words, it is desirable for the Department of Health to demonstrate the importance of such work, and it then should be the responsibility of the organization, industry, etc., to adopt it as a regular part of their health program. The Department of Health is definitely interested in the case found by such means, and so long as the important case is reported and placed under proper supervision, we are eager to see as many agencies as possible set up their own survey program. A few examples may be cited to show how this principle has worked out over the years.

A mass survey was made of pupils in the four city colleges some years ago. The prevalence of disease was about $^4/_{10}$ per cent, which was not as productive as in surveys among persons over 20 years of age. There is, however, a definite educational value for surveys among these students, for at an impressionable age they are made to realize that tuberculosis is a real problem, and that there is a definite method of preventing it. Accordingly, we recommended to the Board of Higher Education that a continuation of such studies was desirable, but that our limited funds would have to be directed toward other groups where the prevalence rate was five or more times as high, and where our funds would render the greatest good to the population as a whole. The Board of Higher Education now requires a chest x-ray of all students on an annual basis. They are paid for by the students. The college employs a competent clinician to read the film. Since the Department of Health must determine the eligibility of the person to remain in the school with a tuberculous lesion, all such cases are referred to us for review. Thus, the five city colleges are now operating a sound case-finding program. The Department of Health is made aware of those with latent or manifest lesions.

In 1939, our first survey for organized labor groups was conducted among the members of the Furriers Joint Council. In that study, the Department of Health assumed the entire financial responsibility of the survey. In 1943, when the employment of these workers was at an all-time high level, they felt that they were threatened with a greater tuberculosis risk than previously, and they petitioned us for another survey on the original basis. As funds were not available to the Department to conduct this study, the Furriers Joint Council, through its own funds and a small charge per member, financed the entire operation, with the exception of the re-examination of those with manifest lesions. This latter part of the job was done by the Department of Health as its contribution to tuberculosis control.

Over 50,000 workers in unions have been surveyed by us in the past. Some unions have wanted repeated surveys, but only the Furriers Joint Council has seemed to want them badly enough to finance the venture. These various unions did, however, to our knowledge, pay out some $10,000 in sick benefits, hospital care, etc., to their members found to have tuberculosis in the surveys originally done by us.

In 1942, the Department set up a joint mass

survey program in industry with the Queensboro Tuberculosis and Health Association. The latter organization assumed the responsibility for promotion, and we the conduct of the actual survey at our entire expense. It became necessary for us to withdraw later, but the Queensboro Association has continued the complete survey with their own resources, which includes the survey phase and a consultation clinic for the evaluation of the case found on the survey x-ray. Since the organization is operated on its own, their work in industrial organizations has resulted in Management's paying a considerable part of the cost. All significant cases found in these surveys have, of course, been reported to the Department of Health.

In 1943, a somewhat similar plan was developed by the New York Tuberculosis and Health Association with the Department of Health. It differed, however, in that all cases found to be suspicious or apparently active on the survey x-ray are referred to our Central Chest Clinic for review and classification, the procedure being similar to that used in our own mass surveys. As this Association did not have a consultation clinic that could re-evaluate the cases found by x-ray survey, it seemed unnecessary to set up such a service when the facilities of our Central Chest Clinic were readily available.

Developments in one of the surveys sponsored by this organization offer another opportunity for sharing the responsibility with Management. This particular organization has a competent medical service with adequate facilities to do the re-examination following the survey x-ray. This will mean that our central clinic will not need to examine cases detected in the survey, but that [illegible] ses and report to us

Health Service has recently conducted a mass survey among employees of the O.W.I. and the Port of Embarkation in New York City. This plan developed as a request on the part of the O.W.I. and the Port of Embarkation through Federal channels. The United States Public Health Service, however, would not proceed unless the Department of Health would be responsible for the follow-up of significant cases. We therefore arranged that the Department of Health would assume the responsibility for appraisal of those cases with significant lesions and the indicated supervision for their contacts. The Department also offered counsel on the advisability of patients with apparently inactive lesions continuing in their present occupations, when from the nature of their lesions more desirable occupation was indicated.

Thus the Department has been able to demonstrate the value of mass surveys in tuberculosis in a wide variety of population groups, and, furthermore, it has seen some of the organizations served adopt a program of their own. The Department continues its interest and assistance, particularly in the case with significant tuberculosis, and it continues to aid and abet in an ever-increasing case-finding program that will reach farther and farther into the community and supplement in a substantial way the rather limited amount of such work that could be done through existing resources of the New York City Department.

Summary

1. The mass chest x-ray survey has been a consistent part of the tuberculosis control program of the New York City Department of Health.

2. Mass x-ray surveys and routine chest clinic examinations of the Department over the past ten years have reached an estimated half million individuals.

3. The effectiveness and value of the mass survey is determined by the availability of facilities to promptly and properly classify the significance of the lesion found on the survey x-ray. This has been done by the Department of Health before a case is referred to a physician or to the district clinic.

4. The Department of Health assumes the responsibility for all significant cases found. This responsibility may be shared with physicians or others so long as they are able to carry out the provisions of the Sanitary Code. In such cases, the Department requires biannual reports until such time as the case may be considered to be arrested. There have been three major objectives in our survey program:

A. To demonstrate the prevalence of disease according to age, sex, race, and general economic status.

B. To demonstrate an efficient method of conducting a survey.

C. To stimulate the interest of others to set up within their own organization facilities to provide a regular periodic service.

5. The first two objectives have been accomplished to a satisfactory degree. The third objective has been accepted, and there is every reason to believe that in time an increasing number of organizations will assume their responsibility in this most important enterprise.

Discussion

Dr. Ralph M. Vincent, *Binghamton*—There is no doubt that Dr. Edwards' report on the mass chest x-ray survey which has been carried on in New York City demonstrates the value of such a program as a case-finding procedure in tuberculosis control. The discovery of several thousand cases of clinically significant tuberculosis among apparently healthy individuals brings us face to face with the realization that there is an immense amount of work to be done before the disease can be eliminated or even satisfactorily controlled.

For some years lack of funds, personnel, and equipment has necessitated the limitation of our case-finding efforts to a large extent to the examination of contacts of known cases of tuberculosis. Although we believe this to be the most fertile field for the discovery of new cases of tuberculosis, reports of x-ray surveys such as Dr. Edwards has made emphasize the need for extension of our search for cases to other groups of the population whenever the necessary facilities are available.

During the past two years a mass survey has been in progress in industrial plants located in Broome County. To date approximately 13,500 films have been interpreted and the yield of clinically significant tuberculosis has corresponded very closely with Dr. Edwards' findings—about 0.6 per cent.

We have been impressed by the fact that very few of the cases discovered in the survey had been reported previously. Another encouraging feature of the work was that most of the cases were in the early stages of the disease.

In our locality officials of several industries became interested in securing x-rays of employees and contributed toward the purchase of portable equipment and the cost of operation. The service is without cost to the employee, on company time, and on a purely voluntary basis. The response has been excellent.

Reports of chest pathology are forwarded to the District Office and are referred to the proper county or city health agency for follow-up.

Dr. Edwards has stressed the necessity of prompt re-examination of persons with suspicious or significant lesions and we are endeavoring to improve our methods to this end. Our procedure is to notify the personal physician of the employee relative to the survey findings in his patient. The employee is urged to consult his physician for further examination and advice. There is some resultant delay which in many instances is longer than is desirable, but this seems to be unavoidable under the present circumstances. These are all people who are working regularly and in most instances feel physically fit. Physicians are extremely busy and it is difficult to arrange for examination at a mutually satisfactory time. Much of this difficulty probably would be eliminated if patients could be referred directly to clinics.

Diagnosed cases are immediately put under supervision and an attempt is made to secure examination of family contacts as soon as possible.

Eventually it is planned to locate the x-ray equipment at a place which may be reached conveniently by applicants for employment in industries in which the workers have been examined. The pre-employment x-ray should prevent the introduction of open cases in a plant where they would be a potential source of infection to workers already examined and found to be tuberculosis-free.

Dr. Edwards has described a profitable case-finding procedure which can be carried on efficiently, and our task now seems to be outlined in the third major objective which was mentioned, namely, to stimulate interest in this project among other organizations. Certainly, it is only through cooperation of health agencies, official and nonofficial, labor, industry, and all those interested in community betterment, that tuberculosis can be controlled and eventually eliminated.

Dr. William Siegal, *Albany, New York*—For more than ten years New York City, under the leadership of Dr. Edwards and his coworkers, has been the scene of mass x-ray surveys of different population groups. What the objectives have been, what results have been attained, and how such surveys and related activities can be integrated with the general tuberculosis control program have been ably set forth in Dr. Edwards' paper. Such a wealth of material has been presented that to discuss all the different points would take too much time and detract from the effectiveness of a worth-while contribution. One or two points, however, might be emphasized.

Dr. Edwards, at a recent meeting, presented a discussion entitled "Case Finding Is Only the Beginning." What profits it to find a lot of new cases with no facilities or preparations to carry out the next logical steps? In planning and arranging for such projects, especially in industry, the physical arrangements and actual x-raying do not constitute the entire project. In promoting such programs in upstate New York, the Tuberculosis Division of the State Department of Health has strongly recommended that such projects be thought through to the end and that arrangements be completed and understandings be reached with management, labor, organized medicine, official and unofficial agencies, for the provisions of needed supervision and therapy for the workers found to have tuberculosis, for family assistance where necessary, and even in some cases rehabilitation and job security. Furthermore, in fitting mass x-ray surveys, especially of industrial workers, into the entire tuberculosis control program, the associated problems of pre-employment x-rays and of periodic resurveys are receiving increasing consideration.

In the description of the mass x-ray survey pro-

Director, Division of Tuberculosis, New York State Department of Health.

gram in New York City and how it has been integrated with the already established services of the Tuberculosis Bureau of the Health Department, there is presented an excellent demonstration of the place and importance of such a service in the general control program. With minor modifications a similar plan could probably be adapted to any community where comparable conditions, population concentrations, public-health organization, and leadership and geographic areas existed; that is to say, the larger cities with progressive health departments. It will be noticed that the important feature, as it should be, of the plan in New York City is the further follow-up and control of the newly discovered cases through the various strategically located clinics conducted by the Tuberculosis Bureau. There is one political unit in this city, one public health agency—the Health Department—and one set of standards to follow.

In upstate New York, because of the large number and great variety of local and health organizations, it is understandable that somewhat different methods than those outlined by Dr. Edwards would have to be employed to obtain similar results. One of the important considerations is that funds have not been available to the State Health Department to conduct such special surveys. Nevertheless, this did not prevent the Department from promoting them on a local basis, and in the past three years, many persons have been examined. A large number of these surveys have been sponsored by local volunteer agencies. Films are interpreted locally by the members of the staffs of local public-health agencies or tuberculosis hospitals, or by the members of the staff of the Division of Tuberculosis. The names of the individuals whose films, interpreted in the Central Office, indicate evidence of pulmonary tuberculosis or other intrathoracic conditions are referred to the appropriate district health offices to institute necessary follow-up and such supervision as is indicated by the follow-up examinations. When such projects are handled entirely on a local basis, the follow-up is a local responsibility. The point is that essentially all efforts are made to obtain the supervision of those found to need it.

As for the results, they agree substantially with those of Dr. Edwards. Approximately 6 to 7 of every 1,000 individuals are diagnosed as having clinically significant tuberculosis. Subsequent follow-up further reduces this number to 2 to 3 of every 1,000 [illegible] treatment.

Dr. J [illegible] came to Ne[illegible] the Bureau of Tuberculosis was on a part-time basis and it was quite inadequate in personnel and in clinic equipment. Dr. Edwards, through clear vision and hard work, has built a Bureau with clinic facilities to be proud of. He has taken the leadership and responsibility and yet has welcomed the assistance and cooperation of other agencies. Dr. Edwards has played an important part in the development of mass case-finding of tuberculosis.

As one listened to this paper one might get the impression that the accomplishments of the Bureau of Tuberculosis in the City Health Department have been easily won. This would be an incorrect impression. The problems to be met with in tuberculosis work in the city of New York have been as great as in any other community. The splendid advance has been made in spite of difficulties.

I do not agree with those who are disturbed that the case-finding of tuberculosis will get ahead of the hospitalization and sanitorium care facilities. Even if such facilities are not now available for all cases found, the person who realizes that he has tuberculosis is more likely to take better care of himself and be more on guard against spreading his infection than if he is ignorant of the fact that he has the disease.

Besides this, the recognition of new cases will add pressure to the demand for more adequate hospital care.

Dr. John H. Korns, *White Plains, New York*—What has been the experience in New York State as to the liability of employers for compensation in case tuberculosis is found among workers? I ask this because a neighboring district has met with objection to mass chest x-ray surveys in industry by the employers who fear they may become involved with great expense if employees are found to be tuberculous

Dr. Allan Hurst, *New York City*—Dr. Plunkett has raised the question as to whether the Department of Health should divide the responsibility of the supervision of tuberculosis cases with other agencies.

The Department of Health is the only agency that should be responsible for the supervision of tuberculosis cases and any work which is done by other agencies on such cases should be cleared through the Bureau of Tuberculosis. This is the policy that has been followed for the past many years in New York City and cooperation is secured by conferences with responsible persons in charge of such agencies. This is especially true in the field of rehabilitation and there is a constant interchange of opinions between the Department of Health and these voluntary agencies. Dr. Edwards' paper, however, stresses the necessity for industry's assuming the cost of survey work among its own employees.

The fee for the x-ray is usually divided between management and the employee to the mutual satisfaction of both. It has been found from experience that when the employee contributes a small sum, his interest is heightened to the extent that he is anxious to follow up the finding of the pathologic lesion in his chest x-ray. All cases found in such surveys are reported to and followed by the Bureau of Tuberculosis, Department of Health.

Dr. Korns has asked about what responsibility management assumes after the finding of the case of tuberculosis among the employees. In those instances in which the lesion appears to be stable and the man is permitted to work, there has been no difficulty in persuading industry to continue the man at his employment with supervision of his case by either the Health Department, the medical division of the plant involved, or private care. In only a few instances have we heard that management has paid for the care of active cases of tubercu-

losis. Certain progressive organizations, such as the Metropolitan Life Insurance Company, have excellent sanatorium facilities, and other plants with good medical units have been able to do a great deal for the care and rehabilitation of their employees who have developed an active tuberculous process. It is to be hoped that other plants will develop some such scheme in the future for care of this type.

THE "AGE LIMIT" AGAIN

"We must avoid inbreeding in our surgical societies."

A truism, certainly, and no one would dispute it. The trouble is that, like most clichés, it has become almost meaningless through constant reiteration.

Commonly it expresses a sense of impatient irritation that posts of honor are not more quickly open to an ambitious young man who has just stepped over the threshold of the profession. If only the "old men" (meaning those of 50, 60, or 70, according to the age of the complainer) would get out of the way, new blood and new energy could be poured into the veins of this or that society and it would forthwith bound forward with youthful vigor.

Sober common sense reveals the absurdity of such thinking. The profession of surgery is practiced by men of many stages of maturity and many degrees of skill, and years are by no means a trustworthy measure of either maturity or skill.

To make fullness of years a prerequisite for the assumption of responsibility is deplorable, of course. Plenty of our younger men earn the right to honor before their hair turns gray. We should find better ways of using such men in positions of responsibility and leadership.

But it is even worse to equate fullness of years with senility and to force arbitrarily into retirement men who attain a given number of years of living. That is a strange denial of facts every surgeon knows from his own practice and experience. We all know that old age sometimes swoops down upon a man of 40, rendering him sclerotic of body and set of mind, and sometimes passes over, with inexplicable carelessness, a man of 60 or 70, leaving him sound and hale, with all the vigorous mental power of youth. Titian painted better at 90 than he did at 40, and had he been subject to a "retirement" ruling for artists, the world would have been deprived of some of the greatest masterpieces ever painted. All of us know of instances where great contributions to surgery and medicine have come from men beyond the age which many urge as the limit to usefulness. The present war crisis has put back into harness many medical and surgical men who had, for one reason or another, retired from active practice. The job they are doing should be adequate answer to those who urge that years can alone put a limit to a man's usefulness.

Surgery moves forward at a breathless pace. The heights which surgical knowledge reached in the days of Ambroise Paré look to us, from the new heights we have since attained, like the merest foothills. Much of what seemed the last word in surgical technic in the days of Billroth interests us now merely as an antiquarian curiosity. Most of us who have practiced surgery for ten, or twenty, or thirty years look back to things that were taught us in medical school with a combination of smile and shudder—they were so wrong! One of the essential qualities for a good surgeon must be the flexibility of "mental muscle" to enable him to keep abreast of a profession on the move. But it is well to remember that such flexibility is by no means the unique possession of youth.

Cocky James Primose was a physician on the make when he set out to demolish the revolutionary ideas of "little Dr. Harvey." He brought to his task a good deal of the vigor of youth. And James Young Simpson, valiant pioneer in the movement toward hospital improvement in his day, was totally unable to open his mind to the discoveries of young Joseph Lister, which were to play so great a role in removing the horror from surgery and from hospitals.

As we strive to keep our surgical societies from the so-called evils of "inbreeding," it is well to remember these things. Inbreeding comes—and is bound to come—when control of a surgical society passes into the hands of men seeking security rather than truth, prestige rather than service to humanity.

When that happens those in power tend to draw about them men of their own kind until the degeneration of the body is complete. But there will be young men as well as older men in such a group. No easy application of an arbitrary retirement rule can break their stranglehold.

The difficult task we must keep always before our eyes is that of checking within our surgical societies the inbreeding of ideas which have no place there. We can do it only as we learn to utilize fully the capacities of the young men and the middle-aged men and the older men in our ranks, as the army uses both the strength and brawn and resilience of youth and the seasoned wisdom of old campaigners.—*Max Thorek, in Journal of the International College of Surgeons, July–Aug., 1944*

FURTHER OBSERVATIONS ON ONE-DAY TREATMENT OF SYPHILIS WITH FEVER AND MAPHARSEN

NATHANIEL JONES, M.D., Surgeon (R), JOSEPH L. HUNDLEY, M.D., P. A. Surgeon (R), ALLEN E. WALKER, M.D., Assistant Surgeon (R), U.S.P.H.S., CHARLES M. CARPENTER, M.D., * STAFFORD L. WARREN, M.D.,* Rochester, New York, and HENRY HANSON, M.D.,† Jacksonville, Florida

PRELIMINARY results in the treatment of early syphilis with fever and mapharsen have recently been published.[1] The present report extends observations on the original group of 280 patients for a period of eight months and also includes data on the treatment of an additional 141 patients observed for a minimum period of three months.

Procedure

Selection of Patient.—Patients selected for the study are limited to those with clinical evidence of early syphilis who deny previous antisyphilitic treatment. The diagnosis is verified by darkfield and serologic examinations. Contraindications to this type of therapy are active pulmonary tuberculosis, heart disease, class II and class III, active renal disease, peripheral vascular disease of any type, and extreme obesity. The majority of the patients treated thus far were young adults in the age group from 15 to 24 years; 77 per cent were Negro; 23 per cent, white; 44 per cent, male; and 56 per cent, female.

Examination and Preparation of Patient.—The patient is admitted to the hospital on the afternoon of the day prior to treatment and given a general physical examination. A chest radiograph and an electrocardiograph are made whenever indicated. A urinalysis and a test for hemoglobin are the only laboratory examinations carried out routinely. Before treatment, the patient is hydrated orally with approximately 3,000 ml. of water and is given a total of 12 Gm. of sodium chloride in 4-Gm. doses at approximately four-hour intervals. No special dietary precautions are observed. Breakfast is permitted on the day of treatment.

Treatment.—The treatment consists of the concurrent use of fever and mapharsen. The amount of drug and the time of administration in relation to the fever have been based on results obtained in the treatment of experimental syphilis in rabbits.[2] Because the animal experiments have shown that fever increases the toxicity of mapharsen, smaller amounts of the drug were employed for the treatment of the first series of patients in order to determine safe limitations of the procedure.[3] Three schedules of treatment have been used.

Administration of Mapharsen.—Schedule A: Mapharsen in the amount of 1 mg. per kg. of body weight is administered during the induction period of the fever, but before the temperature reaches 39.5 C. (103 F.). The calculated amount of drug is dissolved in sterile triply distilled water and injected intravenously.

Schedule B: Mapharsen in the amount of 1 mg. per kg. of body weight is injected intravenously in the evening, and fever therapy is carried out the following day. A second intravenous injection of 1.5 mg. of mapharsen per kg. of body weight is given at the termination of the fever. The calculated amounts of the drug are dissolved in sterile triply distilled water and injected intravenously.

Schedule C: Mapharsen in the amount of 2 mg. per kg. of body weight is administered at the termination of the fever. The drug is dissolved in distilled water as above and then added to 250 ml. of 5 per cent glucose in a 0.85 per cent solution of sodium chloride and is injected intravenously by the drip method. This procedure requires about fifteen minutes and is usually completed by the time the temperature has receded to 40.5 C. (105 F.).

Fever Therapy.—At 7:30 A.M. on the day of treatment, the patient is placed in a Rochester Radiant Energy Cabinet.[4] The specific gravity of the blood plasma is used as a guide to insure a normal fluid balance during fever.[5] The temperature is gradually elevated to 41.1 C. (106 F.) during a period of two hours and is maintained at that level for five hours. The rectal temperature is recorded continuously by means of a resistance thermometer and is also checked periodically with a clinical thermometer. At ten-minute intervals the pulse rate, respiratory rate, and temperature are recorded. During the fever the patient is given from 300 to 400 ml. of fluid per hour by mouth. Throughout the treatment the patient is under constant supervision

* No recrudescence of symptoms.
[1] One mg. of mapharsen per kg. of body weight administered during induction of fever.
[2] One mg. of mapharsen per kg. of body weight administered twelve hours prior to fever; 1.5 mg. of mapharsen per kg. of body weight administered at termination of fever.
[3] Two mg. of mapharsen per kg. of body weight administered at termination of fever.

of a nurse especially trained for this type of therapy.

At the termination of the five-hour fever, the cabinet is opened to permit defervescence, which usually requires about one hour. The patient is transferred to bed and the temperature is observed hourly until three normal readings (37 C. or 98.6 F.) have been recorded. No restrictions are placed on the patient other than rest in bed for several hours. The majority of patients are discharged from the hospital on the morning following the day of treatment.

Observations Made on Patients After Treatment. As described in our first report,[1] patients are to be followed for a period of five years, returning to the clinic weekly during the first eight weeks, monthly for the following six months, every three months during the next year, and annually thereafter. At each follow-up visit, observations are made for clinical evidence of syphilis and blood is collected for a quantitative Kahn test. Spinal fluid is collected for examination either before the patient leaves the hospital or at the first return visit.

Results

To date a total of 662 patients have been treated by the three methods described. This report, however, covers only 421 patients who have had no treatment for syphilis either prior to or following the specified treatment with fever and mapharsen. Seventy-eight of these patients treated according to Schedule A have been observed from twenty-two to thirty months. One hundred and thirty-seven patients treated as outlined in Schedule B have been followed twelve to twenty-two months, and the remaining 206 treated by means of Schedule C have been observed from three to nine months (Table 1).

Of the 78 cases treated according to Schedule A, 15 (19 per cent) showed clinical relapse, 11 occurring within the first four months. A serologic relapse occurred in only one patient. Six of the patients were reinfected.

Of the 137 cases treated according to Schedule B, 13 (10 per cent) have shown clinical relapse to date; and 3 (2 per cent) developed a serologic relapse. There were 2 cases of probable reinfection in this group.

Of the 206 cases treated according to Schedule C, only 16 (8 per cent) have shown clinical relapse to date. Serologic relapse was observed in 5 instances (2 per cent). As yet none of the cases have been considered as reinfection.[2]

As was anticipated, the best results were obtained on patients with the seronegative primary form of early syphilis. Only about 10 per cent of the patients treated with Schedules A or B showed clinical relapse, and as yet none have occurred in 5 patients on Schedule C.

Eight (35 per cent) of 23 patients with secondary syphilis treated with Schedule A have shown a recurrence of lesions. On the other hand, far better results were obtained with Schedules B and C.

With the former schedule, 8 (14 per cent) of 55 patients developed clinical relapses, and with Schedule C only 9 (12 per cent) of 73 patients developed relapses.

Fewer clinical relapses occurred following the treatment of early latent syphilis than following the treatment of early syphilis. The relapses

to date for Schedules A, B, and C are 9 per cent, 4 per cent, and 1 per cent, respectively.

The serologic tests for syphilis carried out subsequent to treatment have shown a similar pattern of reversal regardless of the schedule of therapy. A marked decrease in reagin in the blood of patients with primary and secondary syphilis occurred during the first two months after treatment. Thereafter, the disappearance of reagin was much less rapid. In the case of patients treated for early latent syphilis, the positive serologic test was reversed more slowly than in early syphilis.

Discussion

The results obtained from continued observations on patients treated with fever and mapharsen provide further evidence that this mode of therapy compares favorably with other forms of intensive therapy for early syphilis. In our preliminary report[1] the results with Schedule C appeared superior to Schedules A and B. Schedules B and C, employing approximately twice as much mapharsen as Schedule A, now appear to be more effective. A valid comparison cannot be made between the use of Schedules B and C because of the shorter period of time patients have been observed after treatment with the latter schedule. The data at present, however, suggest that Schedule C, in which 2 mg. of mapharsen is given at the termination of the fever, is less effective in the treatment of seropositive primary syphilis than Schedule B, in which 1 mg. of mapharsen per kg. of body weight is injected prior to the fever and 1.5 mg. is injected at the termination of the fever. Twenty-four per cent of the patients with this type of the disease failed to be cured with Schedule C, whereas only 14 per cent failed to be cured with Schedule B.

None of the patients treated by these methods showed evidence of nephritis, a complication reported by Thomas, Wexler, Schur, and Goldring[6] to occur subsequent to the concurrent use of fever and arsenicals. It should be pointed out, however, that the total dose of mapharsen which these investigators administered to their patients was far in excess of the amount employed in the procedures described herein.

The majority of relapses, both clinical and serologic, occurred during the first three months after treatment, most of them developing in patients with secondary syphilis. The cases listed as reinfection met the criteria of possible reinfection as set forth by Stokes, Cole, Moore, O'Leary, Parran, and Wile.[7] Relapses are unusual after the first four months, but the final outcome cannot be predicted until the end of the five-year period of observation.

As previously pointed out, the concurrent use of fever and mapharsen in the treatment of syphilis offers a number of advantages. The treatment can be completed within eight hours, and the entire period of hospitalization averages only about forty-eight hours. Of importance is the fact that the patient is usually able to resume work the day after leaving the hospital. Laboratory tests such as chemical examinations of blood and liver and kidney function tests are unnecessary. Under the present arrangement, the cost of treatment is about $30 per case. Severe complications, such as arsenical dermatitis, hepatitis, encephalopathy, or renal damage have not occurred among the cases treated. It was necessary to discontinue treatment in only 3 per cent of the cases.

Summary

Continued observations on the original group of 280 patients as well as on 141 additional patients corroborate preliminary findings that the combined use of fever and mapharsen is effective in the treatment of early syphilis as well as in early latent syphilis.[1] Better results have been obtained with Schedules B and C, in which larger amounts of mapharsen (2.5 and 2.0 mg., respectively, per kg. of body weight) were employed than in Schedule A. The results from the use of Schedules B and C are approximately comparable except in the treatment of seropositive primary syphilis, in which B appears to be superior.

Discussion

Dr. Evan W. Thomas, *New York City*—It is a sign of progress when discussions about the place of education in the control of venereal disease turn from exhortation and abstractions to scientifically reported data of actual accomplishment. For that reason Dr. Carpenter's paper is of unusual significance. The results of the poster campaign are so striking that the experiment deserves widespread attention. It is noteworthy that the best results seem to have come from the posters.

This study is being carried out in cooperation with the Division of Venereal Diseases, U.S. Public Health Service.

Appreciation is extended to Miss Helen Bradley and to Miss Mary Niland, Record Analysts, U.S. Public Health Service, for their work in the presentation of the above data.

As most of my time is spent in the care of patients with syphilis, I would like to devote the rest of this discussion to the paper of Dr. Jones and his coworkers. These investigators deserve special commendation for having started their work with animal experiments. This enabled them to plan their one-day treatment of early syphilis in humans more intelligently than would otherwise have been possible. Two factors stand out in their treatment: (1) the relatively small amounts of mapharsen used; and (2) the restriction of high temperatures to five hours.

From my experience these precautions were wise from the standpoint of the safety of treatment. Whether they are justified from the point of view of therapeutic results will be discussed later. In my opinion the hazards of mechanically induced fever are greater than have generally been reported. When patients are properly selected and under the care of experienced personnel it is probable that mechanically induced temperatures of 105 to 106 F., without the addition of arsenical drugs, can be maintained for eight or ten hours with reasonable safety in most cases. Existing statistics from highly trained staffs of experienced workers prove this; but it must be recognized that the fatalities which have resulted from such prolonged fevers in numerous hospitals rarely find their way into the literature. When fever is combined with mapharsen, as Dr. Jones has pointed out, the risk of treatment is increased. Our experience at Bellevue Hospital with combined electropyrexia and mapharsen therapy confirms the general principles which Dr. Jones and his coworkers have established concerning its toxicity.

With a two-day plan of treatment which consisted of four injections of about 1 mg. of mapharsen per kilogram of body weight each, and seven hours of mechanically induced fever of 105.8 F., we encountered severe though transient damage to the kidneys. We subsequently had little difficulty with a five-day plan of treatment which consisted of one daily injection of 0.06 Gm of mapharsen and two sessions of four hours of fever at temperatures of 105.8 F. Evidently, from the report given this morning, this five-day treatment was unnecessarily long. Unfortunately, our work at Bellevue Hospital with electropyrexia had to be abandoned for lack of technical assistants. Granting that our experience with this type of therapy has been limited, I have not been particularly impressed with the results achieved by our two-day treatment.

With our two-day schedule, which was not unlike schedule B of Dr. Jones and his coworkers, except that we gave more mapharsen and more hours of fever, we did not have as good results as with more extended schedules of therapy. Of 48 patient who received the two-day treatment 28 were observed for more than six months. Of the 28 patients kept under observation for more than six months, 5 relapsed, and 2 still have blood Wassermann titers greater than 8, the percentage of satisfactory results being only 74.7. Of 55 patients given the five-day treatment 36 were observed for more than six months; relapses or reinfections occurred in 4, and 2 still have blood Wassermann titers greater than 8, the percentage of satisfactory results being 83.3.

In compiling our statistics no differentiation was made between relapses and reinfections. From my experience with well over 2,000 rapid-treatment courses for early syphilis, it is true that most relapses occur within the first six months after treatment, and reinfections are probably much more frequent than relapses after six months of follow-up. Nevertheless, careful analysis of our relapses or reinfections raises questions which make me hesitate to distinguish between them in compiling statistics.

But even if the reinfections are grouped with the relapses, the results of treatment by Schedule B in Dr. Jones' report compare favorably with most other types of rapid treatment. I am not entirely clear whether all of the patients listed in the table given by Dr. Jones were actually kept under observation. For comparative purposes it seems to me desirable to state in all statistics how many patients in a series were lost within the first six months of follow-up and how many were kept under observations for six months or more. It also seems desirable to give some information about the number of patients with persistently positive serologic tests. But, in spite of my curiosity about these points, I am convinced that the authors of the report on a one-day treatment for early syphilis are to be congratulated both for their scientific approach to the problem and for their apparent success so far.

Dr. B. E. Roberts, *Poughkeepsie, New York*—I believe that it may be of interest to point out, although this is by no means an original observation, that while, on a strict percentage basis, rapid methods of syphilis treatment may not offer quite so much hope of cure to the individual patient as the standard methods, the aggregate result of the rapid method may be much better from a community standpoint. The reason for this is that experience has shown that a large proportion of patients do not complete their treatment under the standard methods, while very few would not complete their treatment if a rapid method is used.

NO CURE FOR LEUKEMIA

"There is no new drug which offers any hope in the treatment of acute leukemia (a fatal disease in which there is a marked increase in the number of white blood cells)," the *Journal of the American Medical Association* for December 9 says in answer to an inquiry.

They add, "Reports of cures of new treatments of leukemia appear frequently in the press. The index of one large newspaper contains seven reports of new treatments for leukemia in the past six years; none of these have proved successful. If a specific agent for leukemia is discovered, it would undoubtedly receive prompt recognition in the *Journal*."

EVALUATION OF CERTAIN EDUCATIONAL PROCEDURES IN A PROGRAM FOR THE CONTROL OF VENEREAL DISEASE*

CHARLES M CARPENTER, M D **, Rochester, New York, and MILLARD E WINCHESTER, M D ,† and ALLSTON GOURDIN, M D ,† Brunswick, Georgia

KNOWLEDGE of preventive measures for the control of disease fulfills its ultimate purpose only when it is available to and utilized by the people for the protection of their health Information is now adequate to prevent and control most of the communicable diseases, nevertheless, many of these maladies are still rampant The venereal diseases are an outstanding example Recognizing the importance of education in venereal disease control, the United States Public Health Service and other agencies have broadened their programs to include education Among the challenging needs in this field are (1) the dissemination of information on venereal diseases to the groups with the highest rate of infection, (2) the teaching of venereal disease education in schools, and (3) the evaluation of educational methods

In carrying out venereal disease programs in a Southern community for the past several years, attempts have been made to evaluate the educational procedures employed These include principally the assistance of health committees in Negro churches, venereal disease education in Negro schools, and the use of venereal disease posters in public lavatories

Glynn County Project

Educational Program.—Three years ago an intensive project directed toward the community control of gonorrhea was undertaken in Glynn County, Georgia, at the Board of Health in cooperation with the University of Rochester School of Medicine and Dentistry and the United States Public Health Service The population of this county, which normally is approximately 20,000, one half being Negroes, has doubled since the war Adequate facilities were first made available for diagnosis and treatment The community was then made aware of the prevalence of gonorrhea the available facilities, and the newer methods of therapy In fact, every measure was taken to encourage patients to seek examination by private physicians or at public clinics Articles appeared regularly in the press giving information on the special venereal disease problems in the community and announcing the program and the facilities offered Radio programs prepared and presented by the staff working on the project were broadcast weekly for a period of six months Talks and discussions on gonorrhea were presented by physicians before the local civic clubs, at Negro theaters, and in churches

Widespread use was made of venereal disease handbills and posters, designed to meet the specific needs of this community The posters bore a conspicuous, brief message directed toward a five-point program for the prevention and control of gonorrhea (Fig 1) Early in the program they were distributed in person as widely as possible, particularly among Negroes who had assembled in groups about the community, at theaters, and on street corners Later, they were posted in public lavatories throughout the community, in large industrial plants, dormitories, and recreation centers of the war housing projects, "juke houses," hotels, restaurants, pool rooms gasoline stations, and tourist camps

Negro churches were utilized as centers for the dissemination of information on venereal disease A health committee, consisting of the minister as chairman, and two young men and women, was formed in each church A community Negro health committee, comprising a physician, a dentist, a school principal, a prominent business man, and one of the leading ministers, was selected to cooperate with the Board of Health in carrying out the venereal disease program and to assist with the direction of the educational work of the church health committees Physicians and nurses from the Board of Health met with the church health committees monthly or bimonthly to teach them the facts about gonorrhea Suitable printed materials were distributed to committee members, who conveyed the information to the membership of the church by arranging discussion meetings, distributing literature, and affixing posters in public lavatories

An effort was made to incorporate the teaching of venereal diseases in the Negro schools Cooperation was extended by the superintendent of education and the principals of several schools to undertake an educational program in the fifth to twelfth grades Support of the parents was readily obtained through the already organized church health committees First, an

GLYNN COUNTY BOARD OF HEALTH
HAS 5 POINTS OF INFORMATION TO

STOP GONORRHEA

(THE CLAP)

1. Gonorrhea is a common disease among young men and women.
2. Sulfathiazole pills, a new drug, taken by mouth usually cure gonorrhea in one week.
3. Don't waste money on patent medicines. They will not cure gonorrhea.
4. Gonorrhea and syphilis are two different diseases. Sulfathiazole pills will not cure syphilis.
5. The pills for gonorrhea may be obtained from your family doctor, or from your Health Officer.

FIG. 1

attempt was made to determine the knowledge of venereal disease among children from 12 to 18 years of age. An unannounced written examination, consisting of five basic questions, was given to 471 pupils (Table 1).

To determine the educational value of posters, one was designed to include pertinent facts concerning the prevalence, cause, mode of transmission, prevention, and treatment of venereal disease (Fig. 2). The posters were placed in the school lavatories without attention being directed to them. Six weeks after the information was made available in this form, the same examination was repeated unannounced.

Results and Evaluation of Educational Methods.—The effectiveness of educational methods is at best difficult to assess, because of numerous uncontrolled factors. In the present study, the evaluation was based upon (1) questioning of patients to determine the medium that directed them to the venereal disease clinic, and (2) comparison of knowledge of venereal disease among school children before and after displaying posters in the lavatories, as measured by written examination.

As a method of directing patients to venereal disease clinics, the use of posters in public lavatories has proved more effective than all other methods. Interview of 604 patients who applied voluntarily for examination and treatment revealed that 461, 76 per cent, reported as a result of having read the poster (Table 2). Of the 461 patients whom the posters directed to the clinic 297, 65 per cent, had venereal disease. Two hundred and sixty were men and 37 were women. With regard to race the numbers were approximately equal; 145 were white, 152 colored.

M. E. Winchester, M.D., Commissioner of Health — C. M. Carpenter, M.D., Special Consultant, U.S. Public Health Service — J. S. Wilkerson Principal

The first unannounced examination given to pupils in the fifth to twelfth grades revealed a dearth of accurate information on venereal disease, even among the older students. The class averages ranged from 15 per cent in the fifth grade to 63 per cent in the twelfth grade (Fig. 3). In general, boys possessed more knowledge than girls. There was evidence that even the younger children knew of the existence of venereal diseases, and that they are caused by "germs." The methods of spread, prevention, and treatment, however, were poorly understood by all.

Re-examination of the pupils six weeks after the posters were affixed in the lavatories showed a marked increase in knowledge, demonstrating that this simple method had resulted in the acquisition of reasonably accurate information. Class averages improved from 20 to 300 per cent (Fig. 3).

The health committees in Negro churches likewise proved effective in the educational program. An accurate measure of the assistance rendered by this group cannot be made. In Vance County, North Carolina, however, where the educational program at the present time consists only of the effort put forth by the church

committees, the attendance at the venereal disease clinic has markedly increased and the three Negro physicians report that many more patients are seeking examination and treatment. Furthermore, public discussion at churches and cooperative efforts among members have tended to remove the stigma attached to these infections. The support of the church was instrumental in paving the way for carrying out the educational programs in the schools.

Evaluation of the Use of Venereal Disease Posters in Public Lavatories

For many years, placards have been employed in public lavatories by state and municipal health departments to direct attention to venereal disease. A survey was made of the materials used by all state health departments and by thirty-seven of the largest cities in the United States. In response to inquiries as to the use of such aids, their value, and a request for samples, replies were received from forty-five states, from Puerto Rico, Hawaii, and the Virgin Islands, and from twenty-six of the thirty-seven cities.

Eighteen states and twelve cities reported that venereal disease posters were not used in public lavatories. Of the twenty-seven states and fourteen cities reporting the use of placards, most were found to be of similar type and based upon information prepared by the Division of Venereal Diseases of the United States Public Health Service. Twelve states and seven cities designed their own posters (Table 3).

The posters were evaluated for their effectiveness in directing patients to seek medical care for the diagnosis and treatment of venereal disease, and were studied from the point of view of content, design, and composition. The majority were found to be unsatisfactory principally for the following reasons: the information was *not stated clearly and simply; too much information* was crowded into a small space; arrangement and composition were poor; posters lacked *appeal in the form of color or design; the type* was too small, or was so varied as to cause confusion; and the material was unsatisfactory.

In response to an inquiry as to the value of posters in public lavatories, health commissioners and venereal disease control officers, with two exceptions, supported the belief that this medium was useful. One commissioner of health made

AVOID VENEREAL DISEASES

1. Gonorrhea and syphilis are two different crippling venereal diseases common among colored young men and women. Of every 1,000 colored men in the State of Georgia, 327 between the ages of 18 and 38 have syphilis. Even a greater number of men and women have gonorrhea.
2. Venereal diseases are caused by tiny germs which usually spread from person to person by sexual intercourse.
3. Prevent venereal diseases by not having sexual intercourse until after marriage.
4. *Venereal disease can be cured with new drugs. Consult* your family physician, Board of Health or school principal, for more information.

THIS PROJECT IS BEING CARRIED OUT UNDER THE DIRECTION OF THE GLYNN COUNTY BOARD OF HEALTH IN COOPERATION WITH THE GEORGIA DEPARTMENT OF PUBLIC HEALTH AND THE UNITED STATES PUBLIC HEALTH SERVICE.

M. E. WINCHESTER, M. D. ..... Commissioner of Health
C. M. CARPENTER, M. D. ..... Special Consultant, U. S. Public Health Service

FIG. 2

the statement that low prevalence of venereal disease in his state made this type of education unnecessary. The replies indicated that the present materials were not satisfactory and that improvements and suggestions would be welcomed.

Experience in Glynn County led to the design of a different type of poster. For those interested in this medium, a few principles found successful are outlined. The poster must have some means of getting and holding the attention of the reader sufficiently long to convey the message. Thus, to reach a reading public of limited education, it must be simply worded, brief, and have some striking feature. To come to the attention at the psychologically appropriate moment adds to its value. This fact was early recognized by the "quacks," who selected the public lavatory as a site for dispensing information on "Female Weaknesses" and "Special Diseases of Men."

In our experience, a poster 9 by 12 inches, printed in a boldface type sufficiently large to be read at a distance of from 5 to 8 feet, is a satisfactory size for this purpose. An inexpensive bond paper has proved more suitable than cardboard or metal because of the low cost and ease of posting. Wallpaper paste has been found to be the best method of affixing the poster to the

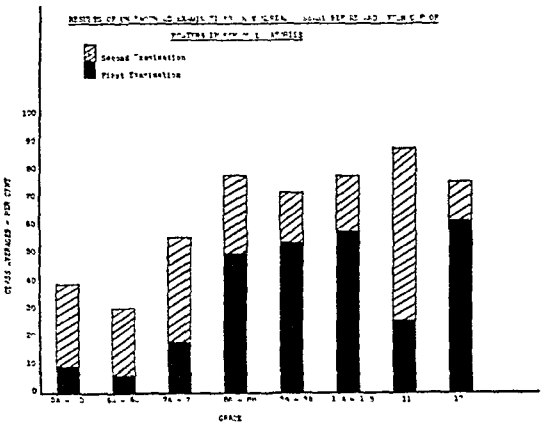

FIG. 3

wall, because the poster may be quickly attached and easily removed with no damage to the wall.

Location of the poster is also of importance. The best sites are over the washbasin, on the back of the door (so when the door is closed the poster will be in front of the toilet), on a partition at the side, or over the urinal.

Most important are content and composition. A conspicuous word or phrase in large boldface type in color will be sufficient to arrest attention and identify the nature of the information. Details should be printed in sufficiently large type to be easily read, but without crowding. General statements should be avoided and as much specific information as possible included.

It is well recognized that all forms of education should be utilized in the control of communicable disease. Because of the nature of venereal disease, however, posters in public lavatories are particularly effective, as evidenced by the success of this method in Glynn County, Georgia. Lavatories in industrial plants and in public places are frequented repeatedly by the young adult group, and particularly men, among whom the incidence of the disease is highest. The privacy of the lavatory permits publication of information that would not be suitable for more public presentation.

The opportunity to disseminate pertinent information by this method should be kept in mind, but, as has been stated, it is essential that improved methods for reaching the groups among whom these diseases prevail should be employed. The possibility of utilizing the public lavatory for the dissemination of information concerning other diseases, particularly gastro-intestinal diseases, must not be overlooked.

Summary

1. Data are presented on the value of posters in public lavatories as an aid in the control of venereal disease. An interview of 604 patients who came voluntarily to the Glynn County Board of Health, Glynn Country, Georgia, for examination for venereal disease disclosed that 461, 76 per cent, were directed to the clinic by posters seen in public lavatories.

2. The value of health committees in Negro churches in carrying out a venereal-disease educational program is discussed.

3. The extent of information on venereal disease among Negro school children is described. A comparison of the results of unannounced written examinations before and after posting venereal disease information in school lavatories showed a marked improvement in knowledge.

4. The results of a survey of the use of venereal-disease posters in public lavatories by state and city health departments are reported.

Discussion

Dr. Theodore Rosenthal,* *New York City*—The authors properly emphasize the importance of education in the control of venereal diseases. Among these needs are:

1. Dissemination of information to groups where the disease is most prevalent.
2. Teaching of venereal disease education in public schools.
3. Evaluation of educational method.

It should be borne in mind that this experiment took place in a rural county in Georgia, with a population of about 20,000, 50 per cent of whom are Negroes. It may be helpful to recall that in the published account of the syphilis prevalence for the first two million selectees, Georgia had a syphilis rate of 133 per thousand; for the white selectees the rate was 39 per thousand and for Negro selectees 327 per thousand.

All of the conventional media for conveying information to the public were utilized. The press, the radio, the spoken word, and group meetings of various sorts, together with posters displayed in prominent places, and later in lavatories in all sorts of public locations.

The utilization of the church by enlisting the aid of the ministers and church leaders was a very wise move.

In considering specifically the role of health education in venereal disease prevention, the question may be raised as to its necessity. Methods of precise

* Director, Bureau of Social Hygiene, New York City Department of Health.

evaluation and statistical yardsticks for health education efforts are not as yet entirely satisfactory Modern public opinion polls however, provide some means of defining and appraising community health education problems Several recent surveys on attitudes and opinions of the public with respect to syphilis and gonorrhea demonstrate a real need for proper information on the subject In addition, venereal disease specialists serving with the armed forces have informed us of the general lack of understanding of many of the basic facts about syphilis and gonorrhea in Army and Navy personnel The rapid reduction in venereal disease rates in military units receiving health education in venereal disease is no longer an isolated phenomenon in the armed forces

It is believed that not enough emphasis has been given in the past to self-control and personal discipline, there are still those who believe that continence is incompatible with good health At this point we can well borrow a phrase from Osler 'Personal purity is the prophylaxis which we as physicians are especially bound to advocate Knowledge is good but wisdom is better

The approach through the schools was courageous and ingenious

The written examination given after indoctrinating the school children is most interesting I should like to ask in what manner children ranging in age from 12 to 18 years were expected to answer question number 3, "How do venereal diseases spread from person to person?' and also question number 4, "How can venereal diseases be prevented?

The principles described for an ideal venereal disease poster are essentially similar to those that have been employed in this area The comments concerning the format and general makeup of a venereal disease poster are excellent Several additional elements might be included

1 A positive statement that venereal diseases are preventable, and avoidable

2 Specific warning to stay away from quacks

3 A statement that promiscuity, or casual sex behavior, is dangerous

To mention specifically a drug, such as sulfathiazole, in a poster designed for the public is not considered in this area to be the best practice It should be sufficient to direct the patient to the physician or clinic, with an added warning that 'Self treatment is dangerous"

In addition to health education conducted in the schools, efforts to control the spread of syphilis and gonorrhea cannot be successful without the help of home and church There would seem to be at least three important ways in which the church can aid (1) Special meetings might be arranged for older boys and girls (2) Church women's groups might consider this as a problem of special importance to parents and others associated with young people in an advisory capacity (3) Some ministers may well feel that this is a subject of such serious moral import that they may wish to speak about it from the pulpit

The vital requirement is to reach as many people as possible, the churches can be of powerful help in this respect, as was so clearly demonstrated during our antidiphtheria campaign of several years ago, as well as in other educational activities Never before have the issues of public health and moral conduct been so clearly and so closely interrelated The increase of venereal disease among young people, some of them mere children, overshadows all other health problems facing us at the present time

I wish to express my appreciation of a most interesting and stimulating presentation, which contains considerable food for thought

Dr Paul B Brooks,** *Albany*—While what I have to say does not relate specifically to control of syphilis it seems an opportune time to put in a word about the general value and importance of public health education I like the term "information" better than "education" People usually are pleased to receive information but not everyone likes the idea of being educated by other people

Whether it has to do with control of a communicable disease or some other matter in which we have to get people to do something in order to secure the results we want, we cannot reasonably expect them to act in the way we want them to unless they have some idea as to the necessity for such action and how it may benefit them as well as other people It is, therefore, an important part of the job of the public health educator, by whatever title, to see that people have the information which may move them to act favorably even if it has to be forced upon them This, in fact, is public health education

I personally feel that public health education—the dissemination of information on public health matters—is one of the most important functions of a health department from the standpoints of getting results I doubt if, even in our own department, we are yet devoting to it the proportion of time, effort, and money which it merits

** Deputy Commissioner of Health New York State Department of Health Albany

US WILL HELP LIBERIA IN FIVE-YEAR HEALTH WORK

At the request of the Liberian Government, the Public Health Service has announced that it has designated an all-Negro mission of eleven American physicians, engineers entomologists and nurses to develop a five-year health and sanitation program in Liberia

Dr John Baldwin West, head of the mission and senior surgeon in the Public Health Service, Granville W Woodson, sanitary engineer, and John P Davies Jr, maintenance superintendent, are enroute to Liberia

The purpose of the mission according to the Public Health Service, will be to bring under control communicable diseases, principally malaria, by the

was the lowest thoracic segment and the highest level attained was the tenth thoracic distribution. In contrast in the cephalad group, the average extent was at the fourth thoracic segment and sensory anesthesia of the lower cervical nerves was recorded as the highest reached. In the two groups the average difference in extent of anesthesia was seven dermatomes (Fig. 2A).

Five individuals were given spinal anesthesia on two occasions. Two of them had no operation. For each patient anesthesia was produced with the directional needle-opening facing caudad once and cephalad another time. The results were consistent and in the same individual the difference in extent of anesthesia averaged eight dermatomes (Fig. 2B).

Two patients were submitted to spinal anesthesia three times. The extent of sensory anesthesia was recorded in one at levels of the first lumbar segment when the directional needle-opening faced caudad, at the second thoracic when it faced cephalad, and at the sixth thoracic when a standard spinal anesthesia needle was used (Fig. 2C). For the other, corresponding recordings were at the twelfth thoracic, fourth thoracic, and seventh thoracic segments. The duration of anesthesia for one of these patients was eighty-five minutes when it was at the low level, sixty-five minutes at the highest level, and sixty minutes when the standard needle was employed. The time was determined as from the beginning of anesthesia until none remained.

Discussion

The foregoing data support the contention that the extent of spinal anesthesia may be influenced and more easily controlled by the use of a directional needle. Such a needle may be used successfully for these purposes when a single injection is done or when the continuous spinal technic is employed.

A directional needle may be inserted at other than a right angle and the resulting spread of injected solution will not be significantly different, but with the standard needle the extent of anesthesia is altered considerably by the angle at which the needle is placed when injections are completed.

When anesthesia is confined to lower segments the same amount of drug will provide a longer action than when a more extensive anesthesia has been produced.

The probability of aspirating cauda equina into the needle is diminished with the use of a directional needle since, when facing caudad or cephalad, the opening being in a different plane, it cannot readily come into contact with the nerve roots.

The rare possibility of having part of the bevel piercing the dura so that fluid may be aspirated and part of the beveled opening without the subarachnoid space so that some of the injection may not enter the canal is obviated by a directional needle.

Summary

Laboratory and clinical investigations on the extent of spinal anesthesia when the injected solution is placed cephalad or caudad by a directional needle are presented. The results indicate that seven or eight dermatomes' difference in sensory anesthesia follow when the solution is injected in one or the other direction.

With spinal anesthesia needles now commonly used, the angle of introduction is a factor in determining the extent of anesthesia. With the directional needle the angle is not important.

The position of the bevel of the standard needle used in spinal anesthesia has no influence on the spread of the injected solution.

The directional needle is useful for the more accurate control of the extent of spinal anesthesia.

Discussion

Dr Irving M Pallin, *Brooklyn*—There is very little that can be added to the excellent paper just presented by Dr Rovenstine The laboratory and clinical investigations indicate painstaking, careful thought and control, which are exemplified by the choice of patients who were to have repeated spinal analgesias and by those in whom surgery was not performed, thus ruling out many of the uncontrollable variables

It is particularly gratifying to find such emphasis placed on the direction of the needle in relation to the long axis of the vertebral column to control the somatic level and also in many instances the duration of the anesthesia This factor is considered so important as to preclude the consideration of the other factors before the direction of the needle has been ascertained after its insertion in the subarachnoid space Many epidemics of unsatisfactory spinal analgesias administered by our surgical staff have been checked by education concerning the importance of the direction of the needle

The use of the "directional needle' helps to simplify and standardize this technic so that the uncertainty of the direction of the needle requires little consideration This needle permits the positive determination of the direction of the solutions to be injected

In comparing the results of low spinal anesthesia with the standard and directional needles it was found that no definite discrepancy existed when with the former a slow injection of 10 per cent procaine in spinal fluid was injected at the rate of 1 cc per eight seconds in the fourth lumbar interspace with the patient in either lateral, reclining, or sitting position Here, as in the speaker's experience, it was found in a series of 83 cases that the average extent of dermatomes involved was the lowest thoracic segments with the highest to the ninth thoracic Six-hundredths and seven hundredths Gm of procaine so injected has lasted sufficiently to permit surgery of the perineum, vaginoplasties particularly, to continue as long as ninety minutes In none of these cases was surgery terminated in less than thirty minutes from the time of injection Only five such administrations were performed with the "directional needle," with analogous results

This type of needle was used to better advantage in high spinal anesthesias It was found that a higher level could be obtained with a slower injection, less volume, within the safe injectable areas (the second, third, and fourth lumbar) than could be obtained with the standard needle with a perpendicular injection The smaller volume is more desirable in that it has been found that the greater the concentration of the drug in a limited area of the spinal cord, the longer the duration of the anesthesia Formerly the same effect was obtained by either directing the needle cephalad with the long axis of the cord at an angle of 60 or 70 degrees to the skin or by inserting the needle in the lowest thoracic intervertebral spaces The latter is undesirable because of the possible mechanical injury to the spinal cord However, it is felt that one should be cautious when attempting high levels with the "directional needle" because the higher levels are much more readily attained with the latter than with the standard needle One can very easily go beyond the desired somatic level With only the limited experience of seven high spinal anesthesias, it was found that with the rate of injection of 2 seconds per cc the level reached varied from the sixth to the fifth thoracic, even though the patient was kept in the supine position after injection

Considerable difficulty was encountered with the "directional needle" in the continuous spinal technic because the needle would tend to rotate in situ while the patient was being changed from the lateral to the supine position It was rather a visual difficulty to ascertain whether or not the needle had rotated after the patient was in supine position To overcome this difficulty, the rubber tubing was connected after the patient assumed the supine position, but this method was unsatisfactory because of the uncertainty that still existed This obstacle was finally overcome by bending the needle at right

From the Department of Anesthesia the Jewish Hospital of Brooklyn

angles at the skin margin and then fixing the shaft to the skin with adhesive tape. This is a costly procedure, because the needles cannot be straightened perfectly and they were, therefore, discarded. A metal flange or pointer was designed so that it would point in the direction of the needle opening and would be attached to the side of the hub. This indicator should show clearly the direction of the aperture in the needle any time during the surgical procedure. Unfortunately, because of present conditions, this needle is still untouched on the instrument-maker's work bench.

The "directional needle" was found to be particularly useful in hemispinal anesthesias. The method previously used was cumbersome and difficult. An attempt was made to point the needle toward the side to be anesthetized by inserting the needle 2 cm. lateral to and beyond the midline of the spinous processes at the interspace selected. The solution was then injected very slowly at about 1 cc. per eight to ten seconds. The "directional needle" has permitted the use of the standard technic of lumbar puncture followed by directing the needle aperture to the side to be anesthetized. A slow rate of injection is still maintained. It has been found that in fourteen nephrectomies, using 14–16 cc. of nupercaine in 1:1,500 solution with the patient in the lateral position and the diseased side uppermost that the hemispinal anesthesia was satisfactory in all cases except for some little hypalgesia of the dependent side. The advantage of this type of anesthesia is twofold—a minimal initial drop in blood pressure and the long duration of the anesthetic without deleterious effects. The average drop in systolic pressure in these cases was 14 mm. of mercury, with a maximum of 20. The longest operation required one hundred and thirty minutes for completion, with adequate anesthesia throughout. In one case there was a drop of 60 mm. of mercury in systolic pressure with a corresponding drop in diastolic pressure, but this occurred forty minutes after the operation was begun and was attributed to hemorrhage. The technic of hemispinal anesthesia was reversed when a hyperbaric solution was used on a patient scheduled for a leg amputation. Here, however, the lateral position was maintained for ten minutes to permit fixation of the anesthetic agent before assuming the supine position.

Some minor difficulties were encountered with the "directional needle." It is felt that the needle is not as sharp as the standard needle, and on three occasions it was discarded because the dura could not be pierced after several repeated attempts. In every case there is a distinct accentuation of the sudden release of resistance that is encountered when the dura is penetrated.

Although there is generally a good flow of spinal fluid, in one case it was necessary to rotate the needle several times before a good flow was established. The final direction of the opening was not the one desired. Theoretically, the cauda equina cannot obstruct the opening when it is directed cephalad or caudad, but it is not beyond the realm of possibility that the posterior dura can overlap the presenting needle and its opening.

It is felt that the directional needle is a welcome addition to the armamentarium of the anesthetist and should become a distinct aid in controlling the level of spinal anesthesia.

"TOPICS OF *THE TIMES*"

Viewed with Alarm. There is no end to the number of normal people who are abnormal. They are even more numerous than the average citizens who are way below the average. This time it is 2,000 Waves in training at Hunter College. Only 15 per cent of them have normal feet, according to the official podiatrists.

It is one more item in the startling logical discoveries which war always seems to bring forth. We all remember the famous Army Intelligence Tests of the last war which were popularly interpreted to mean that the average man's mental powers are far below the average. So, in greater or less degree, we read today of abnormally high ratios of physical disability among men called up for war service, exceptionally high ratios of dental ailments, alarming ratios of mental deficiency, like those against which the Christian Century protests when it accuses the Army psychiatrists of exaggerating the nation's mental ills.

Normal or Ideal? To be sure, it does not sound quite so paradoxical to say that six women in seven have abnormal feet as it does to say that in the matter of healthy feet six women out of seven are below the average. Normal feet, like normal brains or normal eyesight, mean, or should mean, a standard which is independent of statistics. The eye doctor has in mind a "normal" vision. It is not his fault if the first hundred people he examines are "abnormal." A podiatrist has a very clear idea of what a normal foot—meaning a perfectly healthy foot—should be, and it isn't his fault if six women in every seven fail to meet the requirements.

What the experts really have in mind is not the normal but the ideal—and it is much to their credit that they should set their sights so high. Just the same they manage too often to make people forget that they are speaking of an ideal. They succeed in conveying the rather odd notion that most people are abnormal in the sense in which we think of mental abnormality, that is to say, below the average. And thus it happens that the average man's mind is weaker than his own mind, his feet are in much poorer condition than his own feet, his teeth much more neglected than his own teeth.

There ought to be a law. It should be made obligatory on everybody who finds alarming conditions prevailing among the American people to state what his standards are.—*New York Times, July 27, 1944. Reprinted with permission.*

SUBTOTAL GASTRECTOMY IN MEDICALLY RESISTANT ULCERS

J. William Hinton, M.D., New York City

FEW medical programs are complete without a discussion of the ulcer problem, and one might ask why so much emphasis is placed on gastric and duodenal ulcers when they play such a minor role as cause of death compared with diseases of the heart. The U.S. Bureau of the Census reported for 1942 a total of 395,000 deaths from heart disease, or 295 per 100,000; 6,387 deaths from gastric ulcer, or 4.8 per 100,000; and 2,872 from duodenal ulcer, or 2.1 per 100,000. These statistics suggest an interesting discussion regarding the advisability of early surgery for gastric ulcers.

During the past four decades the belief has grown and has become generally accepted that a definite relationship exists between gastric ulcer and gastric carcinoma. As a result, many if not most gastric ulcers are being referred for early radical surgery.

From a previous report[1] of the Fourth Division at Bellevue Hospital we found in 1,256 ulcers that 89 per cent were duodenal. If there were only 2,872 deaths from duodenal ulcer in 1942 as compared with 6,387 deaths from gastric ulcer when the latter do not constitute over 15 per cent of the total number of ulcers, it makes one question the advisability of such early operations. If carcinomatous changes had already developed in these cases, they would have been included under deaths from carcinoma and not from ulcer.

One has only to read Fogelson's[2] review of the literature pertaining to gastric and duodenal ulcer for the years 1934–1936, inclusive, to realize the state of confusion that exists as to the handling of the ulcer patient. At that time Fogelson found that over 1,000 papers a year are written on gastric and duodenal ulcers. Much that is written lacks practical application, as the life cycle of the ulcer has not been followed for a sufficient length of time to draw any conclusions. Spontaneous remissions last for several months and sometimes for one or two years. Therefore, any report of cures is misleading except in the case of a five-year period of observation.

On several occasions[3–6] we have reviewed the cases in the ulcer clinic of the Fourth Medical and Surgical Divisions of Bellevue Hospital and have given our indications for conservative and operative treatment for both gastric and duodenal ulcers.

After more than fifteen years' experience in this clinic we are more than ever convinced that if there is a dictum for the treatment of ulcers it should be: more mistakes are made by too early rather than by too late surgery.

During the years 1942 and 1943 I operated upon 44 patients at Bellevue Hospital and 41 patients at Post-Graduate and other hospitals. As the same indications have been used for all these patients, it would seem worth while at this time to discuss the operative pathology in the medically resistant patient and the rationale of subtotal gastrectomy for this type of ulcer.

Of the 85 patients 19, or 22 per cent, were suffering from gastric ulcer and 66, or 78 per cent, from duodenal ulcer. This is consistent with the review of the cases at Bellevue Hospital for the period of 1928–1942[1] at which time we found that of the total number of cases in our clinic, 89 per cent were duodenal lesions and 11 per cent gastric, while of those referred for operation 73 per cent were duodenal and 27 per cent were gastric. The higher percentage of patients with gastric ulcers admitted to the hospital is due to the fear that the gastric lesion may be carcinoma. There were three deaths, or a mortality of 3.5 per cent.

The good end results of surgery in both gastric and duodenal ulcers depend chiefly upon thorough medical management by a physician with the background to understand the ulcer patient. If the surgeon would take only those patients whom the internist cannot relieve by dietary measures, the results from surgery would be most gratifying.

Indications for Surgery

The one real indication for surgical intervention is *uncontrollable pain.* There are other indications which are frequently used and will be discussed, namely, pyloric stenosis, recurrent hemorrhage, penetrating ulcers, and lack of cooperation on the part of the patient under medical management.

Pyloric obstruction is still referred to in the literature as a true indication for surgical intervention. The stenosing and obstructing ulcer has recently been reviewed by Allen,[7] who states that the stenosing lesion "finally becomes a mechanical problem and the patient seeks help because he can no longer absorb nourishment to maintain life. The onset of such a condition is a gradual one, and the end-stage is reached so insidiously that one often finds that the stomach has become enormously dilated. It is interesting that such an organ, emptying infinitesimal

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

amounts of its contents into the duodenum, can exist within a person and create so little distress." In the two clinics with which I am associated, it has been our experience that a stenosing or obstructing ulcer not accompanied by pain does not require surgical intervention. These patients can be relieved by medical management, and obstruction does not occur provided they remain free from pain.

Wilkinson[8] emphasizes that an obstruction of three months' duration or less will respond satisfactorily to medical management but in the case of an obstruction which has lasted three months or longer, recurrences are almost certain and operation is usually indicated. He does not mention pain as a factor in causing the obstruction. In our experience, obstruction without pain is due to edema and pylorospasm and not to scar tissue around the pylorus. Since 1932 no patient with so-called pyloric obstruction unaccompanied by severe pain has been referred for surgical intervention, either in private consultation or in the clinics.

Two exceptions to the above statement occurred in 1930 and 1931, when simple closure was done for perforated duodenal ulcers, nine months after operation in one case, and two years afterwards in another; a true organic obstruction developed from the operative procedure, necessitating a short-circuiting operation. Neither of these patients was suffering from pain.

Massive hemorrhage, occurring once or oftener as an indication for surgery is a controversial question. First of all, we do not have a clear-cut line between what constitutes massive and moderate hemorrhage, and a study of the literature reveals the elasticity in the grouping of these cases. However, if we all agree that a red-blood-cell count of 2,000,000 or less, a hemoglobin count of less than 40 per cent, and lowered blood pressure with a moderate degree of shock, constitute massive hemorrhage, then we are obviously agreed that the patient has suffered a great loss of blood.

Surgical management of these patients may be considered under two headings; surgical intervention in the stage of acute hemorrhage, which is occasionally indicated, and second, surgery as an elective procedure to prevent further hemorrhage. My views regarding the first-mentioned type of management have been expressed in previous publications.[9,10] The indications for surgery as an elective procedure are interpreted differently in different hospitals. The point emphasized by Allen[7] as to the dangers of massive hemorrhage in the different age-groups has been fairly universally accepted. That is, in a patient over 45 years of age, the prognosis is serious, while in a patient under 45, massive hemorrhage rarely proves fatal. Blackford and Cole[11] have confirmed this observation. Blackford and Allen,[12] in a report of 151 fatal hemorrhages, record that in only 35 cases, or 23 per cent, was there a history of previous hemorrhage, or, in other words, 77 per cent of the fatalities occurred following the first hemorrhage—an interesting observation, with definite clinical significance. These authors also observed that 34, or 23 per cent of the deaths, occurred at home. In a hospital with an active ambulance service the type of case is different from those in the average hospital. The report of Blackford and Allen[12] indicates that, not infrequently, patients die at home before ever reaching a hospital. They state that fatalities in patients under 45 are rare whether or not patients receive treatment, and that in patients under 40, fatalities are almost unknown. On this point we must disagree. Since 1937, on the Fourth Division at Bellevue Hospital, I have had occasion to operate upon three patients who were medical failures, having had chronic ulcers for periods averaging from five to fifteen years. These patients were suffering from intractable pain and were being prepared for operation on the surgical wards, when they had massive hemorrhages. Amazingly enough, all of them occurred within twenty-four to forty-eight hours of the day set for the elective operation. This group of cases included two duodenal ulcers perforating into the pancreas, and one gastrojejunal ulcer eroding into the transverse mesocolon and the pancreas. All three patients were saved by operative intervention. Massive blood transfusions were given before, during, and after operation, and a subtotal resection was performed in each case. The patients were 27, 37, and 42 years old, respectively. Two other patients with whom we had had no previous contact were admitted as emergencies. One of them, 44 years of age, had a duodenal ulcer and the other, 33 years old, had a gastric ulcer. A subtotal resection was performed in each instance. The former patient died, the latter lived. There has been one other case in our division, a gastric lesion that resulted fatally while the author was out of town, but this case was proved by autopsy to be not an ulcer but a small ulcerating carcinoma.

From 1928 to 1937 we encountered an average of thirteen massive hemorrhages a year at Bellevue Hospital, according to the definition of massive hemorrhage as previously described, and there was a medical mortality of 10 per cent. During the years 1937–1943, inclusive, I had occasion to operate upon 14 patients suffering from massive hemorrhage which could not be controlled by repeated transfusions. These patients as a group received anywhere from 2,500 to 8,500 cc. of blood, but instead of improving, they

became worse, and it was necessary to resort to surgery in order to save their lives. In this group we lost but five cases of massive hemorrhage, after surgical intervention.

The management of the patient who has had a massive hemorrhage, or even two or occasionally three massive hemorrhages will depend not so much upon the fact that he has had one or even three massive hemorrhages as upon the x-ray findings and his clinical history. From my experience, the patient with a massive hemorrhage who is not suffering pain of the chronic intractable ulcer seldom, if ever, requires operative intervention. In 1943 a physician, who is now 59 years of age, suffered a massive hemorrhage from a duodenal ulcer. Seventeen years previously he had had a massive hemorrhage and had been asymptomatic during the period between the two hemorrhages. He was advised by his physician that an operation was indicated. The x-rays revealed a duodenal ulcer *without crater, and I strongly* urged this patient not to be operated upon. It has now been nearly a year since his second hemorrhage and he is asymptomatic and doing his normal work.

If the patient is suffering severe pain associated with massive hemorrhage, then the indications are present for operative intervention. The hemorrhage is merely another argument that his condition has progressed to such a degree that he will obtain no further benefit from conservative measures and may possibly endanger his life by a sudden hemorrhage from erosion through the superior pancreaticoduodenal artery.

The *penetrating* or *perforating duodenal ulcer*, as diagnosed roentgenologically, does not necessarily constitute a true indication for surgical intervention. Here, again, we must rely on the clinical evaluation of the symptomatology. If the patient has had an ulcer for years, with intractable pain, then the indications are obvious, but if he has had an ulcer for only a short period of time, and it proves to be a penetrating ulcer, medical management will very frequently relieve the symptoms and the niches will disappear.

The following case was referred to me for operation. The patient was a young man, 24 years of age, with a history of ulcer of two months' duration. Roentgenograms had revealed a penetrating posterior duodenal ulcer and the internist and the roentgenologist had both advised operation. After seeing the patient in the hospital I advised against operation and recommended medical management. After three weeks on the surgical ward the niche disappeared, the symptoms were relieved, and the patient has remained well for three years. The indication, therefore, for surgical intervention in the penetrating ulcer can be decided only by the clinical course, and not by the roentgenologic appearance of the lesion.

Patients who will not cooperate under medical management should not be operated upon. If the surgeon accepts this type of patient for operation the results from any surgical procedure, whether it be a gastroenterostomy or a subtotal resection, will be most unsatisfactory.

I feel rather strongly about the elasticity of these indications for surgical intervention because in a high percentage of the patients on whom I have had the opportunity to operate during the past fifteen years, I have frequently done the third, fourth, fifth, and in one case the sixth stomach operation. I have questioned the indications for the primary procedures after evaluating the patient's history.

Of the 85 patients upon whom I have operated during the past two years, 19, or 22 per cent, had been previously operated upon and were surgical failures, because of either the poor selection of the site of anastomosis between the small intestine and the stomach, or the development of a gastrojejunal ulcer following gastroenterostomy. Of these nineteen surgical failures, three were due to a malplaced anastomosis. In two of these cases, the anastomosis had been made between the terminal ileum and the stomach in each instance, 4 to 5 feet from the ileocecal valve, and the patients were suffering from malnutrition. In the other case the colon had been anastomosed to the stomach, and, as the surgeon thought he had done an anterior gastroenterostomy, he completed the procedure by anastomosing the colon to the jejunum. This patient went for several months following this operation before diarrhea developed. Interestingly enough, closure had been done two years previously for a perforated ulcer, and the patient had only some minor complaints. He was told that he could be made perfectly well by an operation. Fortunately, he was made well but it took a second operation to accomplish it. Therefore, we cannot let such instances go uncommented upon as a cause of failure in surgically treated patients.

Three of these nineteen surgical failures were caused by the continous pain following gastroenterostomy from the original ulcer, and thirteen were caused by the development of gastrojejunal ulcers subsequent to gastroenterostomy. Nine of these gastrojejunal ulcers occurred within six months to ten years following gastroenterostomy for chronic duodenal ulcer, and four developed following closure and gastroenterostomy for acute perforated ulcer. Gastrojejunal ulcers are more likely to develop after gastroenterostomy for acute perforated ulcer than for chronic ulcer.

The question always arises as to why gastro-

jejunal ulcers develop. It would seem there are two answers to this question. One is that if the anastomosis between the stomach and the jejunum is placed some distance from the ligament of Treitz, that is, 10 to 12 inches and even further, the patient is more likely to develop a gastrojejunal ulcer. It might appear to the operator that the anastomosis was not done so far distally, but during the course of secondary gastric surgery such malplaced stoma are seen. Second, and perhaps more important, is the fact that gastroenterostomy for chronic adherent duodenal ulcer will seldom, if ever, give any lasting relief, since a short-circuiting procedure has been carried out on a complicated ulcer. It is for this type of lesion that we find it necessary to do a subtotal resection.

Technic of Operation

Considerable confusion exists as to what is implied by subtotal resection. It is difficult to ascertain whether the surgeon is referring to subtotal resection of the stomach, leaving the ulcer *in situ*, or subtotal resection of the stomach, removing the ulcer *in toto*. A high percentage of surgeons do not remove the adherent duodenal ulcer, but only the stomach, and consider the result from this procedure as satisfactory as from removal of the ulcer. From my observation, I believe it is necessary to remove the ulcer, and this can always be done if the surgeon has had a reasonable amount of experience and is careful in his dissection.

If we accept the concept that achlorhydria is the goal in subtotal resection, then there is a definite reason, in all instances, for removing the pylorus and the adherent ulcer. Edkins[13] and Koch, Luckhardt, and Keston[14] have shown experimentally that the hormone "gastrin" is produced and thrown into the blood stream by the pyloric mucosa and effects the secretion from the cardia and fundus of the stomach. Because of the similar action of histamine upon the gastric mucosa, several authors believe this hormone to be histamine. However, recent work on isolated and denervated gastric pouches with histamine-free extracts has demonstrated the true hormone character of the internal secretion of the gastric mucosa.[15]

Results

There is little doubt that in those cases in which a subtotal resection of 60 to 75 per cent of the stomach is done and the duodenal ulcer is left *in situ*, the follow-up results are far from satisfactory. This point has been stressed by Friedell, Shaar, and Walters.[16] They state that "while the prognosis as to ultimate cure and certainly as to the immediate relief is favorable, it surely does not present the same chance of a complete cure that pyloric removal does," and they cite a case in which the pyloric portion of the stomach and the duodenal region were not removed, but the gastric mucosa was dissected from the remaining pyloric stump. Analysis of the gastric contents three weeks after operation revealed 10 to 15 units of free hydrochloric acid in the gastric section which increased to 60 units after the administration of 0.5 mg. of histamine. They believe that neglect to remove the pyloric portion of the stomach was a factor in the failure.

Kiefer[17] has elaborated upon this point in reporting 222 subtotal resections for peptic ulcer. He emphasizes that 49 were for gastric lesion and 173 for duodenal ulcer. "In 30 cases, because of technical difficulties and their attendant risks, the duodenum and pylorus were not included in the resection, the distal transection being placed proximal to the pylorus, as recommended by Finisterer in cases in which removal of the duodenum is too dangerous. In this group there were seven recurrent ulcers and three cases of postoperative hemorrhage. This relatively high incidence of unsatisfactory results has led to speculation regarding the role of the pylorus and the antrum, since there is evidence that a hormone is evolved in the pars pylorica which stimulates the fundic glands to produce acid. However, actual evidence indicating that failure to remove the pyloric end of the stomach was solely responsible for the recurrence of the ulcer is rather meager. A postoperative gastric analysis after an Ewald meal was done in 24 cases of this group with the finding of free acid in 13 cases, which is approximately the same proportion as that found in the combined group of duodenal ulcer cases. The fact that the surgeon had decided against the attempt to remove the pylorus was an indication that this group represented a particularly severe grade of peptic ulcer and might be expected to show a higher percentage of recurrence."

Whether or not a hormone is secreted by the pyloric end of the stomach, there seems to be little doubt, in some of the clinics with large experience in subtotal resections, that in those cases in which the duodenal ulcer is left *in situ* the results are not as satisfactory as when it is removed. The two previous reports differ in their interpretation. One states that the unsatisfactory result is due to increased acid; the other that it is due to a more virulent type of ulcerative process. If the latter opinion is correct, then there is every reason for removing such a lesion.

Summary and Conclusions

From my observation in the ulcer clinics of the Fourth Division of Bellevue Hospital and of Post-Graduate Hospital I believe that 90 per

cent of ulcer patients whose ulcer is diagnosed reasonably early in its course, that is, within the first year of onset of symptoms, can be satisfactorily managed on a medical regimen if the patients can be persuaded to cooperate The 10 per cent who fail under medical management will require a radical surgical procedure, as these patients do not submit to surgery for simple uncomplicated ulcer but for an ulcer which has penetrated through the entire wall of the duodenum and the floor of which has been formed by the head of the pancreas or the duodenohepatic ligament Of the forty-seven primary duodenal ulcers for which I have operated during the past two years, forty-two were situated at the posterior wall of the duodenum. If you visualize the dial of a clock, 3 o'clock would represent a completely posterior ulcer, and anywhere between 12 and 6 a partial posterior ulcer In only five instances was the ulcer anterior, or between 6 and 12

In evaluating the operations for ulcer which I have performed during the past two years, it would seem to me that even at the present time too many patients are being advised to have an operation and too few are being managed on a medical regimen. When the patient is suffering persistent pain which sedation does not relieve, it is then apparent that medical management will not afford relief and the patient should be promptly referred for surgery.

There is only one satisfactory surgical procedure for the medically resistant ulcer and that is subtotal resection with removal of the ulcer *in toto*

Gastroenterostomy is doomed to failure in these cases as the patient has been referred not for the ulcer per se but for the complication which has resulted from the long-existing ulcer and which, in most instances, is a chronic pancreatitis.

Even at the present time considerable secondary gastric surgery is being done on patients in whom the indication for primary operation was questionable Premature operations are apt to result in failures in a high percentage of cases

The malplaced anastomosis is still an important cause of operative failure in a high percentage of operations for gastric or duodenal ulcers

HARSH MEDICAL TERM

New York's Selective Service Director says he knows scores of cases where men earning $5,000 to $[illegible] a year ... why ... undertake ... vice on that ground These men are neither mentally defective nor insane

... ble words for a comparatively innocent ailment, in the first place?

The man in the street or at the boss's desk does not have in mind the many gradations from mere excitability and emotional maladjustment through the neuroses and the psychoses into acute mental disease Any diagnosis with "psych..." ... o know had by way of countless sensational murder trials where the defense has been insanity. This has been supplemented by the newer popularization of psychiatry in all fields But as a matter of fact the new terminology only makes things harder Once upon a time you could call a man a crank or an old grouch or an absent-minded professor without further serious connotations But in an age that has discovered neuropsychiatry the old crab in the boss's office or the lady with the artistic temperam... innocent and even pleasant word as a substitute for psychoneurosis Our advertising profession is a perfect marvel at such soothing euphemisms A man discharged from military service on the ground, let us say, of "civilian orientation" would stand a much better chance of getting back his old job than if you call him a psychoneurotic In fact his civilian employer might be positively eager to hire back a man civilianly oriented —*Topics of the Times, New York Times, Aug 30, 1944*

Fortunately, it is not necessary to do Rh tests before every transfusion; in fact, such a procedure would serve only to unnecessarily delay the great majority of transfusions. For clinical purposes, cases requiring blood transfusions can be divided into three classes:

1. Patients who have never been exposed to antigen.—This group includes patients who have never had a previous transfusion or pregnancy. In such cases the Rh factor may be disregarded, for, as far as is known, barring one rather unconvincing case report, natural sensitivity to the Rh factor does not occur. For example, the Rh factor may be disregarded when transfusing wounded soldiers or sailors who have not had previous transfusions. In the case of women in the child-bearing age, there is some objection to disregarding the Rh factor; should the woman be Rh-negative and among the 2 per cent capable of being sensitized, a transfusion of Rh-positive blood could serve to sensitize her so that a subsequent pregnancy might result in an infant with hemolytic disease.

2. Patients who have been exposed to the Rh antigen but without clinical evidence of sensitization.—This group includes patients receiving blood transfusions but without untoward reaction, and patients who have been pregnant but have borne only normal children. Such patients, if Rh-negative, presumably are of the common variety that is not readily sensitized, so that presumably they could safely have transfusions of Rh-positive blood. However, since the possibility exists that sensitivity may actually be present but of too mild a degree to cause a transfusion reaction or obvious signs of hemolytic disease in the infant, and inasmuch as such sensitivities tend to increase in degree with each succeeding exposure to the Rh antigen, the best policy in these cases is to test the patient for the Rh factor whenever time permits. In urgent cases, when there is not enough time for such tests, Rh-negative blood of a compatible group should be used, and the patient should be Rh-tested in the interim to prepare for future transfusions, should any be required. If only Rh-positive blood is at hand, a biologic test with 50 cc. of the blood should be done, and if the test is negative, as will almost invariably be the case, any quantity of the same blood can be given safely. The interval of an hour, while waiting for the result of the biologic test, can be used for a plasma transfusion, if the need is great enough.

3. Patients who have been exposed to the Rh antigen with clinical signs suggestive of sensitization.—This group includes patients who have had reactions to previous transfusion, or have given birth to an infant with hemolytic disease, or have had unexplained stillbirths. These cases constitute absolute indications for the use of Rh-negative blood, unless, by careful serologic tests and biologic tests, the existence of sensitivity to the Rh factor can be excluded. Of course, the transfusion reactions may have been caused by pyrogens rather than by intragroup hemolysis, but it is essential to prove that this is the case by Rh-testing the patients and donors. If Rh-negative donors are not at hand, the hazard would be less in these cases if reliance is placed on plasma transfusions until proper tests can be done, and donors that are certainly compatible can be found, rather than chance a blood transfusion from a donor of unknown Rh type.

Hemolytic disease of the fetus and newborn is a peculiar disease in that frequently the infant appears perfectly normal at birth; yet soon thereafter hemolysis of its red cells takes place. If the hemolysis is gradual, as is often the case, the patient merely develops a pallor because of the development of a hemolytic anemia. This may be overlooked until the infant is five to ten days old and the anemia is of such severity—e. g., as low as 20 per cent hemoglobin—that the infant is moribund and it is too late to do anything for him. In milder examples of the disease, no anemia may develop or the anemia may be so slight that recovery occurs spontaneously. At any rate, this manifestation of the disease is amenable to treatment, so that all infants should recover under proper modern transfusion therapy.

In more severe cases, hemolysis is more abrupt, and obvious jaundice results because of the inability of the body to eliminate the products of hemolysis at a sufficiently rapid rate. The jaundice conceals a severe anemia; the hemoglobin may drop as low as 40 or even 20 per cent during the first twenty-four to forty-eight hours of life. Almost all of these infants can also be saved, provided the physician is alert and transfusion therapy is instituted without delay.

Transfusion therapy serves merely to replace the hemolyzed blood and has proved of no value in the speaker's hands for combating other manifestations of the disease. For example, in some cases with little or no anemia, the patients develop a hemorrhagic tendency and die from hemorrhages into the brain and lungs. In still other cases in which there is little or no anemia, the jaundice, which need not be marked, instead of clearing, persists and the patient develops a kernicterus. Usually such infants die, and this would be best in all cases showing this manifestation, because the infants that recover are apt to develop into mentally deficient individuals.

Finally, of course, must be mentioned the cases in which intrauterine hemolysis occurs with resulting death in utero. The infants in such

instances are stillborn, either hydropic, jaundiced, or without obvious evidence of disease.

In the infant with hemolytic disease the paradoxic situation exists of an antigen being present in the body simultaneously with its specific antibody. Almost invariably the infant is Rh-positive, yet he has in his body anti-Rh isoantibodies derived from his sensitized mother through the placenta. For some reason, in most cases the antibodies are prevented from acting until after birth. This has been explained by assuming that the antibodies are stored in the infant's tissues, from which they are released after birth. More recent studies by the speaker indicate that the special nature of the antibody may be the explanation. The anti-Rh agglutinins used for the in vitro tests are probably not responsible for the hemolysis, because these are often not demonstrable in severe instances of the disease, while cases have been reported in which the maternal serum contained high-titered anti-Rh isoagglutinins, yet the infant was apparently normal. The newly described "blocking antibodies" are also frequently absent, as well as the agglutinins in severe instances of the disease. In all cases, however, the mother gives a positive biologic reaction upon the injection of small amounts of Rh-positive blood, indicating the existence of still a third or even more varieties of anti-Rh isoantibody, one of which is probably responsible for the hemolysis of the infant's red cells.

For the transfusions, the maternal whole blood is not suitable because it contains anti-Rh isoantibodies, and transfusions of her blood, unless the plasma is removed, would tend to aggravate the disease. Transfusion of paternal blood or any Rh-positive blood would also merely add fuel to the fire, since the infant's body often contains enough antibodies not only to hemolyze all the infant's own blood but also additional Rh-positive blood that may be introduced by transfusion. The ideal blood to transfuse is Rh-negative blood of the infant's blood group, or better, Rh-negative blood of a group compatible with the mother's serum. In emergencies, group O Rh-negative blood may be used; or, if an Rh-negative donor is not available but a centrifuge is at hand, blood can be drawn from the mother, the red cells washed twice with saline solution, and the cells transfused after resuspending them in saline solution or compatible plasma. This is not as difficult a procedure as it sounds, because the baby only requires small amounts of blood, and the washing of the mother's cells can be carried out in ordinary culture tubes.

Naturally, the blood must be given by the intravenous route; intramuscular, subcutaneous, and intraperitoneal injections are useless. I have never used the longitudinal sinus for a blood transfusion. This, in my opinion, subjects the infant to an unnecessary hazard. When the scalp veins are well developed, citrated blood can easily be transfused into them by syringe with the aid of a 22-gage needle and two-way stopcock. Scalp veins failing, a small incision into the antecubital fossa, or better, anterior and superior to the medial malleolus at the ankle, will always yield a suitable vein. The amount of blood given at one time is usually approximately 10 cc. per pound body weight, although in patients with extreme anemia larger doses may be given. I usually give two transfusions of 75 cc. each, and when we consider that in most newborn infants the total blood volume is about 250 cc., this is sufficient to maintain the hemoglobin at 60 per cent even when all the infant's own cells have been hemolyzed. In the usual case, the infant survives for a time with only the donor's cells in its circulation, but eventually these are replaced by the infant's own cells as they wear out, so that by the time the infant is two or three months old it has fully recovered. If the regeneration of the infant's blood does not keep pace with the elimination of the donor's cells, a third and sometimes a fourth transfusion may be required when the infant is two to four weeks old. In mild cases, on the other hand, a single transfusion may suffice or recovery may occur without any treatment at all.

As part of the treatment, infants with hemolytic disease are not permitted to nurse because anti-Rh isoantibodies have been detected in the colostrum and milk of their mothers. To date, in my personal experience, the lives of twelve infants have been saved by transfusions of Rh-negative blood or washed maternal cells. Subsequent examinations have shown all these infants to be perfectly normal, both clinically and hematologically.

DR. CARL H. SMITH: The subject for discussion can be divided into two phases, namely, the Rh factor in relation to erythroblastosis fetalis and to transfusion.

Erythroblastosis fetalis presents many clinical features, the greater number of which can now be interpreted in terms of the concept of intrauterine isoimmunization. A change in terminology from erythroblastosis fetalis to hemolytic anemia of the fetus and newborn seems justified at this time, and has the advantage of stressing the underlying mechanism. This designation would also include the milder types which are associated with minimal anemia, jaundice, and erythroblastemia, which are noted more frequently because of greater interest in erythroblastosis. The term "congenital anemia of the newborn," heretofore applied in connection with the less severe types

of this disease, would no longer be necessary. It is interesting to note that in this more favorable form of erythroblastosis, the anemia is not noted at birth but becomes manifest during the first week of life. If the maternal anti-Rh agglutinins were present at birth, it is hard to understand why hemolysis should be postponed until the third or fourth day of life. It is possible, of course, that the agglutinins were stored in the fetus and for some reason remained inactive until after delivery. In this case, as Dr. Wiener mentioned, there is the curious circumstance of the simultaneous presence of an antigen and its specific antibody.

Another clinical feature which is difficult to correlate with the isoimmunization theory is the fact that repeated transfusions with Rh-negative blood are occasionally required to maintain adequate blood levels in infants showing manifest erythroblastosis fetalis from birth. Since the infant's cells are Rh-positive, it may be assumed that either in utero or soon after birth a sufficient number of red cells have been destroyed to have produced the anemia and to have exhausted the supply of anti-Rh agglutinins in the process. The persistence of the anemia even for shorter periods than were observed in the days when Rh-positive blood was used and the increasing jaundice are still difficult to interpret except on the basis of the continuous action of maternal anti-Rh agglutinins.

On the other hand, the destruction of fetal red cells by anti-Rh agglutinins elaborated by the mother explains many clinical and hematologic features that were formerly puzzling. Cases of icterus gravis had been encountered in the past in which the anemia and jaundice persisted over such long periods, despite repeated transfusions, that this diagnosis was ultimately questioned and the possibility of an unsuspected blood dyscrasia or some type of obstructive jaundice was considered. In those instances undoubtedly anti-Rh agglutinins continued to hemolyze the infant's red cells, and when susceptible Rh-positive cells were introduced by transfusion, not only was the anemia unimproved, but the jaundice became more intense. The use of Rh-negative blood of the infant's blood group should obviate this difficulty in the future.

While the amount of blood currently administered is approximately 20 cc. per Kg., there is no set rule regarding the frequency of transfusions. Experience has shown that it is unnecessary to maintain the maximum levels of hemoglobin and red cells that characterize the early newborn period. In fact, the administration of excessive amounts of blood in order to keep up these high values may lead to increased hemolysis, especially when Rh-positive blood is used. As pointed out by Potter, the resulting bilirubinemia may actually contribute to kernicterus. In deciding the need for repeating transfusions after the emergency period, the hemoglobin value of the healthy full-term infant may serve as a useful guide. Following the neonatal drop, the hemoglobin in the first two years of life normally ranges from approximately 10 to 12 Gm. per 100 cc. of blood. It may be advisable, therefore, following the initial transfusions, to attempt to maintain a hemoglobin level of 12 Gm. per 100 cc. of blood, which represents the higher value for the thriving full-term infant.

There may be other elements in the blood picture besides the hemoglobin and red count which have to be considered. In an analysis of cases from the pediatric service of this hospital to be published shortly, Dr. Martha Leonard found evidence in favor of vitamin K deficiency as being one of the major causes, although not necessarily the only one, of hemorrhagic manifestations in patients with erythroblastosis. Every infant with erythroblastosis should, therefore, be regarded as an individual problem and in addition to correction of the anemia, appropriate therapeutic measures should be administered to combat particular symptoms.

The advisability of premature delivery to shorten the exposure of the susceptible fetus to destructive antibodies has been suggested in treatment. Potter does not believe that this procedure can be carried out sufficiently early for the infant to escape erythroblastosis. The result might be that the infant already afflicted with erythroblastosis would be subjected to the hazards of prematurity.

Obviously, the ideal method of preventing fetal erythroblastosis should be directed towards removal of the anti-Rh antibodies from the mother's blood during pregnancy. Recently, Broman experimented with the injection of blood from the Rh-positive father but with unsuccessful results. I would like Dr. Wiener to discuss this very important phase of erythroblastosis, since he has already prepared red-cell stromata for treating sensitized Rh-negative individuals.

DR. WIENER: The problem of prevention of erythroblastosis is indeed a vexing one, and we haven't a satisfactory solution yet.

First, with regard to the possibility of desensitizing by injecting Rh hapten, injecting small amounts of whole blood, 5 cc. at a time, would hardly suffice to desensitize the patient. Instead, it might make her more sensitive.

To desensitize you have to inject massive amounts in order to exhaust the antibody-producing mechanism. According to estimations based on our experiments with red-cell stromata, the amount of Rh antigen per red cell is very mi-

nute indeed. I would estimate it at $^1/_{50}$ or $^1/_{25}$ of the amount of A and B antigens per red cell. Therefore, red cell stromata as a source of Rh antigen are exceedingly impure. I should estimate that a good dose for desensitization should contain purified Rh hapten equivalent in amount to that which could be obtained from 500 cc. of blood. Therefore, if we are going to get anywhere we shall have to find a better way of getting Rh hapten. Of course, there is plenty of material available as a by-product from blood plasma, but we have no means of purifying the material in order to extract the antigen. To use crude red-cell stromata would entail the injection of many other extraneous substances which might do harm; in any event, such material would be unpleasant to work with.

As a preventive measure one might advocate eugenic marriages. However, that would be difficult to carry out, because it would be hard to convince a couple not to get married because the girl is Rh-negative and the boy is Rh-positive and there is a remote possibility that she may be the one in fifty who is capable of becoming sensitized. However, if an Rh-negative woman is a sister of another woman who has had erythroblastotic babies, then I think eugenic advice is strongly indicated, because there is a much higher probability of her becoming sensitized to the Rh factor. The ability to become sensitized is hereditary, as shown by my recent observation of two sisters, both of whom had stillbirths due to Rh sensitization.

It is possible to offer an opinion to some of these couples as to their chances of having an Rh-negative and therefore normal baby. If the husband is homozygous for the Rh factor, then every child must be Rh-positive and therefore subject to the action of the maternal isoantibodies. If one or more of the children of such a couple have already been Rh-negative, obviously the husband must be heterozygous for Rh factor and there is a fifty-fifty chance that the next child will be Rh-negative also, and therefore normal.

With the aid of the Rh types one can recognize some of the homozygous men. Type Rh_1Rh_2 is one of the homozygous types. Ordinarily, such individuals must transmit either Rh_1 antigen or Rh_2 antigen to every child. That is, every child in such a family will get one of the Rh antigens and it will therefore be subject to the disease.

There is a certain antigen, Hr, which, if tested for in Rh-positive individuals (type Rh_1) helps us to ascertain whether a man may or may not be heterozygous. This phase of the subject is a bit complicated and more of a laboratory problem than a clinical problem. It is discussed in detail in a forthcoming paper to appear in the *Journal of Experimental Medicine.*

Finally, it might be mentioned that spacing of the pregnancies has proved to be important. If the pregnancies are close together, isoimmunization is apt to be more intense and the diseases will become aggravated in succeeding pregnancies, while if a woman who has had an erythroblastotic baby does not become pregnant again for eight or ten years, she may have a better chance to have a normal child.

DR. C. H. WHEELER: Is it correct to say, Dr. Wiener, that, given an Rh-negative wife and an Rh-positive father, their chances of failing to have a normal child are about one in fifty?

DR. WIENER: With no other information available?

DR. WHEELER: Yes.

DR. WIENER: That is correct, with the following qualification: the first pregnancy almost always yields a normal child, because the woman has not had time to become sensitized, unless the woman has received a previous transfusion of Rh-positive blood.

DR. SAMUEL LEVINE: What percentage of infants at birth and shortly after birth show the anti-Rh antibody in their blood?

DR. WIENER: I have never seen it, nor have I ever tested for it. It is difficult enough to detect anti-Rh antibodies in the maternal serum. It would be still harder to find such antibodies in fetal serum.

INTERN: Why is it so hazardous to use Rh-positive blood?

DR. WIENER: Because, as I mentioned, there is a third type of antibody which gives no in vitro reactions but which can be picked up in the biologic test. For example, I have women who have had erythroblastotic babies who have no agglutinins or blocking antibody in the serum, but when you give them 50 cc. of Rh-positive blood they have a chill and hemolysis, as demonstrated by inspecting plasma.

DOCTOR: That is due to another antibody?

DR. WIENER: Yes.

DR. SMITH: You can only determine it by injection of the blood?

DR. WIENER: That is the only way to obtain an absolutely reliable result; the in vitro tests are less reliable. If the biologic reaction following injection of 50 cc. of Rh-positive blood is negative the woman is not sensitive. If it is positive, she is sensitive.

DR. HARRY GOLD: Is the usual in vitro test for Rh factor hemolysis or agglutination?

DR. WIENER: Agglutination.

DR. GOLD: I take it that when the Rh-incompatible blood is injected, agglutination may occur, yet the reaction is not caused by agglutination, but by the hemolysis.

DR. WIENER: The occurrence of agglutina-

of this disease, would no longer be necessary. It is interesting to note that in this more favorable form of erythroblastosis, the anemia is not noted at birth but becomes manifest during the first week of life. If the maternal anti-Rh agglutinins were present at birth, it is hard to understand why hemolysis should be postponed until the third or fourth day of life. It is possible, of course, that the agglutinins were stored in the fetus and for some reason remained inactive until after delivery. In this case, as Dr. Wiener mentioned, there is the curious circumstance of the simultaneous presence of an antigen and its specific antibody.

Another clinical feature which is difficult to correlate with the isoimmunization theory is the fact that repeated transfusions with Rh-negative blood are occasionally required to maintain adequate blood levels in infants showing manifest erythroblastosis fetalis from birth. Since the infant's cells are Rh-positive, it may be assumed that either in utero or soon after birth a sufficient number of red cells have been destroyed to have produced the anemia and to have exhausted the supply of anti-Rh agglutinins in the process. The persistence of the anemia even for shorter periods than were observed in the days when Rh-positive blood was used and the increasing jaundice are still difficult to interpret except on the basis of the continuous action of maternal anti-Rh agglutinins.

On the other hand, the destruction of fetal red cells by anti-Rh agglutinins elaborated by the mother explains many clinical and hematologic features that were formerly puzzling. Cases of icterus gravis had been encountered in the past in which the anemia and jaundice persisted over such long periods, despite repeated transfusions, that this diagnosis was ultimately questioned and the possibility of an unsuspected blood dyscrasia or some type of obstructive jaundice was considered. In those instances undoubtedly anti-Rh agglutinins continued to hemolyze the infant's red cells, and when susceptible Rh-positive cells were introduced by transfusion, not only was the anemia unimproved, but the jaundice became more intense. The use of Rh-negative blood of the infant's blood group should obviate this difficulty in the future.

While the amount of blood currently administered is approximately 20 cc. per Kg., there is no set rule regarding the frequency of transfusions. Experience has shown that it is unnecessary to maintain the maximum levels of hemoglobin and red cells that characterize the early newborn period. In fact, the administration of excessive amounts of blood in order to keep up these high values may lead to increased hemolysis, especially when Rh-positive blood is used. As pointed out by Potter, the resulting bilirubinemia may actually contribute to kernicterus. In deciding the need for repeating transfusions after the emergency period, the hemoglobin value of the healthy full-term infant may serve as a useful guide. Following the neonatal drop, the hemoglobin in the first two years of life normally ranges from approximately 10 to 12 Gm. per 100 cc. of blood. It may be advisable, therefore, following the initial transfusions, to attempt to maintain a hemoglobin level of 12 Gm. per 100 cc. of blood, which represents the higher value for the thriving full-term infant.

There may be other elements in the blood picture besides the hemoglobin and red count which have to be considered. In an analysis of cases from the pediatric service of this hospital to be published shortly, Dr. Martha Leonard found evidence in favor of vitamin K deficiency as being one of the major causes, although not necessarily the only one, of hemorrhagic manifestations in patients with erythroblastosis. Every infant with erythroblastosis should, therefore, be regarded as an individual problem and in addition to correction of the anemia, appropriate therapeutic measures should be administered to combat particular symptoms.

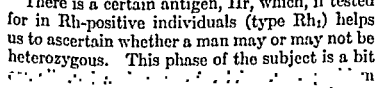
The advisability of premature delivery to shorten the exposure of the susceptible fetus to destructive antibodies has been suggested in treatment. Potter does not believe that this procedure can be carried out sufficiently early for the infant to escape erythroblastosis. The result might be that the infant already afflicted with erythroblastosis would be subjected to the hazards of prematurity.

Obviously, the ideal method of preventing fetal erythroblastosis should be directed towards removal of the anti-Rh antibodies from the mother's blood during pregnancy. Recently, Broman experimented with the injection of blood from the Rh-positive father but with unsuccessful results. I would like Dr. Wiener to discuss this very important phase of erythroblastosis, since he has already prepared red-cell stromata for treating sensitized Rh-negative individuals.

DR. WIENER: The problem of prevention of erythroblastosis is indeed a vexing one, and we haven't a satisfactory solution yet.

First, with regard to the possibility of desensitizing by injecting Rh hapten, injecting small amounts of whole blood, 5 cc. at a time, would hardly suffice to desensitize the patient. Instead, it might make her more sensitive.

To desensitize you have to inject massive amounts in order to exhaust the antibody-producing mechanism. According to estimations based on our experiments with red-cell stromata, the amount of Rh antigen per red cell is very mi-



nute indeed. I would estimate it at $^1/_{60}$ or $^1/_{25}$ of the amount of A and B antigens per red cell. Therefore, red cell stromata as a source of Rh antigen are exceedingly impure. I should estimate that a good dose for desensitization should contain purified Rh hapten equivalent in amount to that which could be obtained from 500 cc. of blood. Therefore, if we are going to get anywhere we shall have to find a better way of getting Rh hapten. Of course, there is plenty of material available as a by-product from blood plasma, but we have no means of purifying the material in order to extract the antigen. To use crude red-cell stromata would entail the injection of many other extraneous substances which might do harm; in any event, such material would be unpleasant to work with.

As a preventive measure one might advocate eugenic marriages. However, that would be difficult to carry out, because it would be hard to convince a couple not to get married because the girl is Rh-negative and the boy is Rh-positive and there is a remote possibility that she may be the one in fifty who is capable of becoming sensitized. However, if an Rh-negative woman is a sister of another woman who has had erythroblastotic babies, then I think eugenic advice is strongly indicated, because there is a much higher probability of her becoming sensitized to the Rh factor. The ability to become sensitized is hereditary, as shown by my recent observation of two sisters, both of whom had stillbirths due to Rh sensitization.

It is possible to offer an opinion to some of these couples as to their chances of having an Rh-negative and therefore normal baby. If the husband is homozygous for the Rh factor, then every child must be Rh-positive and therefore subject to the action of the maternal isoantibodies. If one or more of the children of such a couple have already been Rh-negative, obviously the husband must be heterozygous for Rh factor and there is a fifty-fifty chance that the next child will be Rh-negative also, and therefore normal.

With the aid of the Rh types one can recognize some of the homozygous men. Type Rh_1Rh_2 is one of the homozygous types. Ordinarily, such individuals must transmit either Rh_1 antigen or Rh_2 antigen to every child. That is, every child in such a family will get one of the Rh antigens and it will therefore be subject to the disease.

There is a certain antigen, IIr, which, if tested for in Rh-positive individuals (type Rh_1) helps us to ascertain whether a man may or may not be heterozygous. This phase of the subject is a bit

nal of Experimental Medicine.

Finally, it might be mentioned that spacing of the pregnancies has proved to be important. If the pregnancies are close together, isoimmunization is apt to be more intense and the diseases will become aggravated in succeeding pregnancies, while if a woman who has had an erythroblastotic baby does not become pregnant again for eight or ten years, she may have a better chance to have a normal child.

DR. C. H. WHEELER: Is it correct to say, Dr. Wiener, that, given an Rh-negative wife and an Rh-positive father, their chances of failing to have a normal child are about one in fifty?

DR. WIENER: With no other information available?

DR. WHEELER: Yes.

DR. WIENER: That is correct, with the following qualification: the first pregnancy almost always yields a normal child, because the woman has not had time to become sensitized, unless the woman has received a previous transfusion of Rh-positive blood.

DR. SAMUEL LEVINE: What percentage of infants at birth and shortly after birth show the anti-Rh antibody in their blood?

DR. WIENER: I have never seen it, nor have I ever tested for it. It is difficult enough to detect anti-Rh antibodies in the maternal serum. It would be still harder to find such antibodies in fetal serum.

INTERN: Why is it so hazardous to use Rh-positive blood?

DR. WIENER: Because, as I mentioned, there is a third type of antibody which gives no in vitro reactions but which can be picked up in the biologic test. For example, I have women who have had erythroblastotic babies who have no agglutinins or blocking antibody in the serum, but when you give them 50 cc. of Rh-positive blood they have a chill and hemolysis, as demonstrated by inspecting plasma.

DOCTOR: That is due to another antibody?

DR. WIENER: Yes.

DR. SMITH: You can only determine it by injection of the blood?

DR. WIENER: That is the only way to obtain an absolutely reliable result; the in vitro tests are less reliable. If the biologic reaction following injection of 50 cc. of Rh-positive blood is negative the woman is not sensitive. If it is positive, she is sensitive.

DR. HARRY GOLD: Is the usual in vitro test for Rh factor hemolysis or agglutination?

DR. WIENER: Agglutination.

DR. GOLD: I take it that when the Rh-incompatible blood is injected, agglutination may occur, yet the reaction is not caused by agglutination, but by the hemolysis.

DR. WIENER: The occurrence of agglutina-

tion in the in vitro tests is a strong indication that sensitivity may be present, but this is not entirely reliable, in contrast to the biologic test. There have been cases in which the maternal serum had anti-Rh agglutinins of titer as high as 100 or more, yet the infant, when born, proved to be normal clinically. On the other hand, severe instances of hemolytic disease may occur in the absence of detectable agglutinins.

DR. MARION B. SULZBERGER: The point is that these two common antibodies are closely associated.

DR. WIENER: That is correct. There is close correlation between the occurrence of agglutination in vitro and hemolysis in vivo, but the correlation is not absolute.

DR. WHEELER: All cases which give agglutination are likely to give a reaction. Those which do not give agglutination are not necessarily free of that danger.

DR. WIENER: We now often see cases of women who have had an unexplained stillbirth, years earlier, and we test them and find they are Rh-negative with blocking antibodies. Now the mystery is explained. The stillbirth was caused by hemolytic disease. In 1936 that case would not have been diagnosed as hemolytic disease, but merely listed as unexplained stillbirth.

I can cite for you a case in point. A woman who is Rh-negative had an erythroblastotic baby. The husband was type Rh_1Rh_2. We therefore knew that the next baby had to be Rh-positive and have the disease, so we drew some Rh-negative blood in preparation for the delivery. When the infant was delivered by cesarean section, it looked pale and very weak. We had to give it blood within fifteen minutes after birth or that baby would have been dead. Subsequent calculation showed that the hemoglobin concentration at birth must have been less than 20 per cent. The infant's condition at birth was so desperate that we transfused 150 cc. of blood at one time. It was a pale baby, not jaundiced, and made an uneventful recovery. This case without the benefit of modern knowledge, would have terminated as an unexplained neonatal death.

In a second case, last week, the baby again was expected to be erythroblastotic. At birth everybody remarked that the baby appeared perfectly normal. However, I noticed a certain coppery color to the skin which I have seen in these cases before, and the hemoglobin concentration turned out to be only 75 per cent. Therefore I gave the baby one transfusion of 95 cc. of blood and the hemoglobin went up to 120 per cent. I then performed a biologic test on the mother with 50 cc. of Rh-positive blood because her serum contained no demonstrable antibodies. This was followed in one hour by a sharp chill and the plasma became darker in color, proving that the mother was sensitive to the Rh factor. When the baby was seven days old I received a call that his hemoglobin was again only 75 per cent. If this baby had not had the transfusion at birth his hemoglobin would have been 40 per cent, because 30 per cent of his blood was derived from the Rh-negative donor. This case demonstrates the reliability of the biologic test for detecting Rh sensitization in contrast to the in vitro tests for agglutinins and blocking antibodies.

DR. SMITH: To continue the subject of erythrob astosis, would you tell us, Dr. Levine, if there has been any difference in the mortality figures on the pediatric service in the last year or two, in cases of erythroblastosis with the use of Rh-negative blood as compared with several years ago when transfusions were given in which the Rh factor was unknown? It seemed to me that even in the earlier period, our mortality figures were beginning to decline. I believe the reason for the more favorable results was that the diagnosis was being made a little earlier and transfusions were given more promptly.

Dr. Levine, do you want to give us your experience?

DR. LEVINE: I had my secretary list the number of cases of erythroblastosis fealis, or hemolytic anemia according to the new terminology, and we had, between 1932 and 1938, 32 cases, with 14 deaths, or a mortality of 43 per cent. From 1939 to 1941, a period of three years, we had 25 cases with 9 deaths, or a mortality of 36 per cent. About that time, I think, we began to use Rh-negative blood and in the last three years, 1942, 1943, and 1944, we had 33 cases with only 3 deaths, or a mortality of 9 per cent.

We did not do biologic tests, but we did use Rh-negative blood, and there is this drop from about 35 per cent to 9 per cent in a significant number of cases, so I think the routine use of Rh-negative blood was of some benefit. Presumably, the use of the biologic test in addition to the Rh-negative blood would be even more effective.

Turning to another question, there is some evidence now that would indicate that there is a higher proportion of Rh-negative mothers and Rh-positive babies in those children who have mental retardation. Some recent work in the last year has indicated that apparently this factor may not only produce hemolytic anemia in the newborn but may, in the absence of kernicterus, produce nonspecific mental retardation. In mongolian idiocy, in hemolytic idiocy, and other types this blood pattern occurs in the same

proportion as in the general population, while in those of nonspecific origin the pattern of Rh-negative mother and Rh-positive baby is disproportionately high

DR SMITH Don't you think that possibly points to the fact that the Rh factor is active earlier in fetal life than one suspects?

DR WIENER I have to admit that I have not accepted this report too literally, for the reason that the meager statistics available were rather unconvincing The Rh tests are very delicate, and satisfactory evidence was not presented that the proper controls had been included and the technic employed was impeccable

There is no doubt there are a certain number who do develop mental deficiency from kernicterus That we know from direct evidence Whether the numbers of cases with minor degrees of this disorder are sufficient to swell the numbers of mental deficients so that these can be detected merely by statistical study of the Rh types I question I believe these cases are much too rare to have such an obvious effect

DR SMITH May I go from this phase of erythroblastosis to the transfusions in later life? Dr Stillman, would you care to discuss the transfusion reactions that occur outside the period of pregnancy with relation to the Rh factor?

DR RALPH G STILLMAN It is very difficult to discuss that phase of the subject adequately from our experience, because, among the total number of transfusion reactions which occur in any institution there is commonly no way or no consistent attempt to identify which ones of those reactions are actually hemolytic reactions or incompatibility reactions

When the reaction is frankly caused by incompatibility the patient becomes jaundiced and has hemoglobin or urobilin in the urine There is no question about it, but, as Dr Wiener has already said, many of those reactions, or at least some of them, are, in all likelihood, incompatible reactions I can say that, so far as our experience goes, over a period of twelve years we have had only one instance in which we know that the reaction of incompatibility was caused by the Rh factor

We had a similar reaction in the early days of this hospital, about 1934 or 1935, in which Dr Landsteiner was able to identify an atypical agglutinin in the patient's serum, and we can only assume that that, in all likelihood, was an Rh incompatibility

So far as our experience is concerned, with the exception of only two cases, the Rh factor has caused very little difficulty in ordinary transfusion, even when repeated

I am very glad that Dr Wiener has introduced this question of biologic tests, because our ordinary compatibility tests commonly fail to detect incompatibility due to the Rh factor

In the one case which we have had of a surgical patient, nonpregnant, the compatibility test was positive but in the other cases which we have had in pregnant women the conventional compatibility tests were entirely negative, even though carried out both at room temperature and at 37 C

DR SMITH Dr Reznikoff, have you had any experience with the Rh factor in transfusions in anemia?

DR PAUL REZNIKOFF No Of course, in this institution Dr Stillman does all these duties We come to him when we have a problem

Recently one of the students, Mr Ebaugh, wrote a very good review, which I enjoyed reading very much I hope he will take part in the discussion

There is one thing which strikes me from a hematologic standpoint, and that is that our concern about the Rh factor may lead us to forget that there are other problems in transfusions which have to be solved and which probably depend upon incompatibilities We have today two patients in the hospital who are Rh-positive and go ahead and give them their type blood and don't worry about the reaction if the matching is good As a matter of fact, one of these individuals has had several reactions

I hope we do not get too obsessed with the Rh problem and forget that there are other problems in transfusions which are not solved yet We get reactions in spite of apparent test-tube and hematologic correctness

DR WIENER Referring to Dr Reznikoff's problem of Rh-positive patients having hemolytic reactions, we have been able to solve a large proportion of these cases also First of all, there are more than one Rh factors Persons belonging to one Rh type have, in a few cases, become sensitized by blood of a different Rh type In the scheme of eight Rh blood types the Rh negative type has a position like that of group O among the four blood groups For example, a person in group A can be given group A blood or group O universal donor blood Similarly, a person of type Rh_1 sensitized to blood of type Rh_2 can be given type Rh_1 blood or Rh negative blood, so that in all cases when an Rh positive patient has had a hemolytic reaction it is worth while empirically to try Rh negative blood, and we have successfully solved quite a few transfusion problems in that way

On the other hand, type Rh_1 individuals are of two types some are Hr positive and some are Hr negative If the patient belongs to type Rh_1 and is Hr negative, transfusions from Hr nega-

tive donors are worth trying. If suitable antiserums are not available for making the in vitro tests, biologic tests with Rh-negative and Hr-negative donors can be tried.

In one case of an intragroup hemolytic reaction, I found the patient to belong to group O, type N, and Rh-negative, with anti-M as well as anti-Rh agglutinins in her plasma. This patient was successfully given blood from a group O, type N, Rh-negative donor. Since only one in seven persons is Rh-negative, and only one in five is type N, only one in 35 group O donors would be type N and Rh-negative and therefore suitable for this patient.

Another thing to bear in mind is that the patient may be hemolyzing the donor's blood very slowly over a period of days instead of hours, so while there may be a very slight rise in icteric index the persistence of donor's blood in the patient's circulation may cause confusion in the in vitro tests. Recently, following an intragroup reaction, I typed a patient's blood and found it to consist of a mixture of Rh-negative and -positive blood. This patient had been typed by the laboratory after the reaction occurred and classified as Rh-positive. I felt, however, that the patient was Rh-negative and was slowly hemolyzing Rh-positive blood received by transfusion, some of which still persisted in the circulation. This patient's condition was desperate; the previous transfusions had failed to raise the hemoglobin, which dropped instead to 15 per cent. On my advice the patient was given 1,000 cc. of Rh-negative blood, a massive transfusion; whereas previously after each transfusion the hemoglobin dropped lower, this time the hemoglobin went up and the patient improved markedly. Unfortunately, five days later the patient died of a cerebral embolus, but that, of course, had no connection with the problem.

DR. WHEELER: Dr. Wiener, you spoke earlier of individuals who have never been pregnant and to whom it is perfectly safe to give a transfusion without regard to the Rh factor. That would apply only to the first transfusion which they received, would it not?

DR. WIENER: That is right.

DR. WHEELER: After they have received one transfusion they might have difficulty?

DR. WIENER: Yes.

DR. WHEELER: How long does it take, after a transfusion, for sensitivity to develop in a patient who has never been pregnant and has never had a transfusion before? For example, could you give a transfusion daily for five days without any difficulty?

DR. WIENER: This varies considerably in different patients. As already mentioned, there are two broad groups: patients easy to sensitize and patients difficult to sensitize, of which the former make up 2 per cent. The minimum period which it takes to sensitize is about a week, so if you give a transfusion at one- or two-day intervals, the patient is continually in the negative phase, and while the patient may not be benefited, if of the sensitive type, he or she will at least not be subjected to a dangerous reaction. Incidentally, with regard to patients difficult to sensitize, I don't think that they make up an absolute group, because there are probably none who cannot finally be sensitized. For example, there was a case reported by Drs. Ayer and Kammer in which an Rh-negative patient received more than twenty transfusions before developing Rh sensitivity, and in a case of Dr. Bohrod's a woman gave birth to eleven perfectly normal children and then had three erythroblastotic infants in succession, two of whom died of the disease. The difference between the two groups is one of degree and kind, rather than a real qualitative difference. Similarly, while everybody can become allergic, only a few people are so allergic that they get hay fever from inhaling pollen.

DR. GOLD: I want to ask Dr. Wiener whether he would hazard a guess as to what proportion of all transfusion reactions are likely to involve the Rh factor.

DR. WIENER: That depends on the laboratory technic. If the technician is apt to make errors in grouping, then most reactions will be due to wrong grouping.

DR. GOLD: Let us take the best hospital with the best technicians.

DR. WIENER: In the best hospitals, employing best technics, I would estimate approximately 2 per cent of all blood transfusions are followed by chills. Of these perhaps one out of ten might represent an intragroup incompatibility reaction caused by Rh sensitization

MR. F. G. EBAUGH: I would like to ask Dr. Wiener about Rhy, Rhx, and the St antibody described by the British workers.

DR. WIENER: The St antibody appears to be identical with Levine's Hr antibody already mentioned. Blood factor Rhx appears to be the same as the rare factor named Rh′ by me. In the forthcoming paper to appear soon in *Science*, in addition to the six allelic Rh genes which I originally described, I describe three or four additional rare genes giving reactions intermediate between those of the standard genes. One of these may be the same as the British gene Rhy.

DR. SMITH: Are there other questions?

DR. LEVINE: May I ask, Dr. Wiener, will you just say a word about the secretors and nonsecretors? Is that terminology completely outmoded?

DR WIENER The terms "secretor" and "nonsecretor" apply only to the four blood groups A person in group A, B, AB, or O may or may not have the corresponding group substance in water soluble form in the body fluids and secretions Eighty-five per cent do and 15 per cent do not by heredity Those who do are called secretors because you can demonstrate the group substances in any of their secretions, like saliva Those who do not are known as nonsecretors

DR LEVINE So far as it concerns the Rh factor, are all persons nonsecretors?

DR WIENER As far as we know, barring one report by Boorman and Dodd in England, who claim they detected Rh factor in small amounts in the tissues But so far their report has not been confirmed

DR SMITH The problem of the secretor and nonsecretor only comes up when one deals with an Rh positive mother of an erythroblastotic infant In that case you might blame the A and B factors, if present in the fetal blood and not present in the maternal blood Then the question of secretor and nonsecretor comes up, does it not?

DR WIENER That is right There have been a few cases in which the Rh types were compatible between mother and child, and the occurrence of hemolytic disease in the infant was ascribed to incompatibility with regard to the common blood groups Ordinarily it is assumed that the presence of A and/or B substances in fetal tissues and secretions protects the red cells from the action of maternal anti A and anti-B In some cases, however, the anti A and anti-B of the maternal serum was of such high titer that even if the fetus was a secretor it was felt there was not enough antigen to protect the red cells

DR GOLD I assume that in the administration of plasma the Rh factor is not a problem?

DR SMITH Rh antigen appears to be restricted to the red cells and, if present in the plasma at all, is present in too minute amounts to cause any difficulty

Summary

DR WIENER The practical importance of the Rh factor lies in the fact that certain individuals whose blood lacks the Rh factor, and who are therefore said to be Rh-negative, have the capacity to become sensitized to the Rh factor when exposed to the antigen as a result of a transfusion of Rh-positive blood or a pregnancy with an Rh positive fetus Such sensitivity to the Rh factor manifests itself clinically in one of two ways, namely (1) the occurrence of an intragroup hemolytic transfusion reaction when the patient is given transfusion of Rh positive blood, or (2) the birth of an infant with hemolytic disease or the occurrence of a stillbirth Since, among white individuals, approximately 15 per cent are Rh-negative, the approximately equal incidence of intragroup transfusion reactions and erythroblastotic infants—namely, approximately one in 300 transfusions or pregnancies, respectively—implies that only one in about 40 to 50 Rh negative individuals is readily sensitized to the Rh factor However, as was pointed out, the difference between individuals easy to sensitize and those difficult to sensitize is probably not absolute, so that probably every Rh-negative individual could eventually be sensitized to the Rh factor if exposure to the antigen were sufficiently intense, as a result of multiple transfusions or pregnancies

As was pointed out, intragroup transfusion reactions due to the Rh factor can be prevented by giving Rh-negative patients transfusions only with Rh negative blood While this procedure is imperative in sensitive patients, and advisable in patients receiving a series of transfusions, it is not essential at the first transfusion in an individual not previously exposed to the Rh antigen Thus, wounded members of the armed forces can mostly have transfusions without regard to the Rh factor In the case of women in the child bearing period, however, attention should be paid to the Rh factor, because a transfusion of Rh positive blood into an Rh negative woman might serve to sensitize her and in that way ruin her chances of bearing a normal child

The transfusion therapy of infants with hemolytic disease is similar in principle to the prevention of intragroup hemolytic reactions, except that the infants are passively sensitized instead of actively sensitized to the Rh factor Whereas formerly, when donors were not selected for the Rh factor, some of these infants required a long series of transfusions before the hemolytic process finally stopped, cures now follow quite regularly after two or at the most four transfusions of about 75 cc each of Rh negative blood Dr Samuel Levine's mortality statistics showing a drop in the mortality rate from 36 per cent to only 9 per cent, reflect the improvement in the therapy of the disease The most convincing demonstration of the importance of the Rh factor, however, is the clinically obvious, dramatic life saving effect of transfusions of Rh-negative blood, when infants with the disease are treated

The complications introduced by the discovery that there are three different Rh factors, instead of one, giving rise to eight Rh types instead of merely Rh-positive and Rh-negative, were mentioned Fortunately, 90 per cent of instances of intragroup incompatibility or hemolytic disease

FOUR YEARS OF WAR SURGERY

Some people, including some physicians, have the notion that the calamity of war is offset, at least partly, by war's contribution to the advancement of medical science in general and of surgery in particular. Improvements in the medical service to our wounded men in the present war are due chiefly to the principle of advanced surgical units, to more rapid ground and air transportation, to the use of sulfonamides, to more liberal recourse to blood and plasma transfusions, and to plaster immobilization of soft-tissue wounds. Major General Mitchiner[1] asserts that this improvement is not as great as one would like to believe, especially in the prevention and control of sepsis. Mitchiner says that the "self-congratulatory coma into which some of our 'specialist' colleagues have allowed themselves to lapse is almost without justification." He feels that the slightly wounded should be given precedence of treatment.

These cases constitute 60 to 70 per cent of war wounds; if promptly and adequately treated near the battlefront, most of these men can be returned to the front line. In World War I a large number of wounds were from bullets, whereas those seen in the present war are mainly lacerated wounds of a severe type, the mortality from which is much higher. In the bombing casualties of aerial warfare some 60 per cent of the patients die either as a result of the actual injury plus blast or soon after from hemorrhage and shock due to the severity of the wound inflicted.

While admitting the great part played by the Blood Transfusion Service, Lord Mitchiner feels that there is a tendency to overevaluate blood transfusion to the detriment of older and simpler methods of resuscitation and wound treatment such as hot sweet fluids by mouth, warmth, and morphine. Furthermore, the risk of septic infection from administering blood transfusion on the field of battle and in the street during an air raid is considerable. Blood or serum should not be given intravenously farther forward than the advanced dressing station on the field of battle, the sick

Case Report

UNUSUAL EPHEDRINE REACTION

DAVID LOUIS ENGELSHER, New York City

THE reason for presenting this case, of special interest to the general practitioner, in view of his frequent use of ephedrine, is that this is the first reported instance of ephedrine producing ridging of the nails in addition to an extensive and prolonged dermatitis medicamentosa from a single therapeutic dose.

A careful search of the literature[1-6] fails to reveal any mention of ridging of the nails from ephedrine, although dermatoses are described [1-3] Its significance will be described later

Case Report

Case 1.—T. F , aged 14 years, was referred to me by his family physician for chronic intractable asthma. His attacks, which started when he was 5 years old, were perennial, with very short periods

ceptible to poison ivy, and asthmatic seizures were provoked by nuts, dogs, and the smell of fish. Adhesive plaster produced a contact dermatitis A single dose of ephedrine internally caused an extensive and prolonged dermatitis with ridging of the nails, a rare occurrence which is the basis for this report.

His nose was chronically affected At the age of eight weeks he had facial eczema, which lasted a few months.

A frank family history of allergy was denied, although a cousin possibly was asthmatic The patient was a bright lad who had marked asthmatic and emphysematous findings Otherwise nothing unusual was noted.

Allergy Study.—By the scratch, intracutaneous, and patch tests and elimination methods, sensitivities were found to timothy, ragweed, oak, mixed feathers, horse dander, cottonseed, egg, milk, peanut, rice, perch, and pike

The combined catarrhal vaccine produced a slight reaction within twenty minutes and a moderate reaction in twenty-four hours. Patch tests for adhesive plaster and poison ivy were marked

reaction, but

bar

subside. However, for many weeks later, ridging of the finger nails persisted, with desquamation of the affected skin areas It required several months for the skin and fingernails to return to normal.

Treatment and Progress.—The general rules followed in allergy treatment were carried out, plus the elimination of the specific offenders. Parenterally, a combined autogenous and stock catarrhal vaccine was used, commencing with very small, well-diluted doses (one million organisms per cc) at weekly intervals. Later, the intervals were extended to one month when the condition had im-

, plus the inhalation of

this regimen, and without recourse to potent therapy, the patient's progress was most satisfactory. The emphysema receded markedly, the interval between attacks became longer, and the seizures were less severe. After two years of this therapy, there was rarely an occasion for the use of oral or inhalatory medication, and his condition was improved sufficiently for him to accept a scholarship at an engineering university out of town.

Comment

The significant points of this case report are:

1. Ephedrine sensitivity should be considered in the causes of ridging of the nails, which are numerous[6]

2 A most searching inquiry is necessary, reviewing months of possible contacts, since a single dose of ephedrine may be sufficient to produce, besides ridging of the nails, an extensive dermatosis.

3 A thorough allergy study consists of more than the performance of skin tests. It embraces, besides scratch, intracutaneous, and patch tests, elimination procedures and experience; the knowledge that a negative skin test does not rule out a certain allergen as a factor, as in this case, nor that a positive skin reaction incriminates that material as a present cause Skin tests are an aid in practical hands, misleading in those with limited training.

4. If a trivial dose, as already mentioned, can precipitate so much disease, it is possible that unsolved diseases, such as psoriasis, may be sensitization disturbances not necessarily from something contacted frequently, but from an overlooked occasional allergen. This point raises the ideal procedure in the care of patients, namely, very careful recorded observation over a long period of time.

5 Before prescribing, an inquiry as to drug sensitivities should be made, particularly in allergic patients.

Summary

A case of ridging of the nails caused by ephedrine is described, believed to be the first reported in the

literature. Its significance in the proper procedure of allergic diagnoses is discussed.

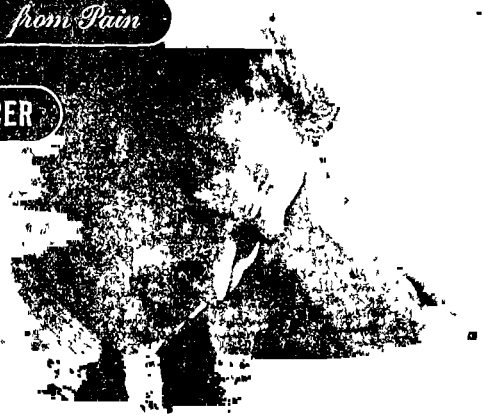
BIRTH UNDER HYPNOSIS

Hypnosis as a means of producing a state of relaxation in which minor operations can be performed has been described but has never become popular. It has been most used in dentistry, but only to a very limited extent.

A recent paper from America on the use of hypnosis in childbirth may give added interest to a matter which is of both practical and theoretical importance. Kroger and deLee* report on 12 cases in which practically the whole of labor was carried out whilst the patient was rendered analgesic and trance-like. It seems that the dissociated condition lasted while forceps were applied. Episiotomy and perineal repair were undertaken, and though the report is not clear it seems that hypnosis was used in other cases in which labor was normal

When it was decided to use this method the gravida was placed in a hypnotic condition by the usual suggestive measures at fortnightly intervals from the sixth month onwards. In the course of these sessions deep hypnotic states were produced, and suggestions that the labor would be painless and convalescence normal were made. During labor itself the hypnotic state was produced shortly after onset, and was continued for as many hours as necessary, during which time the patients were able to micturate, defecate, and bear down as in labor without any hypnosis. The hypnotist could arrange that the suggestions were equally effective if made by the house officer or nurse in charge. It is claimed that to dispense with medical hypnotics and anesthetics is of much importance where complications such as heart disease or hypertension are encountered, and that in perfectly healthy women the absence of medicine is of benefit in the puerperium.

Why, it must be asked, is the practice not more widespread? Would not suggestions made under hypnosis during the latter months of pregnancy benefit many women frightened of childbirth? The efficiency of modern anesthetics and hypnotics, and their rapid effects, obviously appeal more to obstetricians, who are still unable to state the exact moment when labor will begin. There is a vigorous conception that the healthy, normal mother does not expect to be relieved of labor pains which she knows her friends and her ancestors have experienced and largely forgotten, and there is a sort of superstitious belief that the woman who really fears childbirth is a poor specimen, and that to experience such ordeals is a stimulus to character formation. But the obstetrician rightly fears labors more in the neurotically affected and in those with systemic disorders. If hypnosis does what Kroger and deLee claim, should it not be available for these patients?



The real difficulty is probably a practical one: hypnosis suddenly attempted in the maternity bed will be unlikely to succeed. It must be prepared for by preliminary sessions, and that means a regular time-table for the hypnotist and his availability when labor starts. Hence further trials will come from special gynecological units to which psychiatrists with interest in the problems of hypnosis are attached. But the evidence that such collaboration between the gynecologist and the psychiatrist is overdue is daily apparent to both parties. The former is wanting to use the latter for many more purposes than to tell him when termination is justified on psychiatric grounds. Both are interested in the amenorrhea which accompanies anorexia nervosa. Both are interested in the problems of functional dysmenorrhea. Neither has solved the psychological problems of the menopause of the endocrine substratum; why is the menopause so physically and psychologically disturbing in some, so comparatively minor an event in others? Both psychiatrists and gynecologists (as well as the sociologist and anthropologist) are interested in a fuller explanation of the food fads of pregnancy, the recurrent fears about mutilated, malformed, and defective children that the pregnant mother has, and about the reasons given for family limitations. When psychiatrists are more numerous and more trained in field work some of these problems may be tackled and suitable prophylaxis undertaken, as well as more use made of hypnosis as a substitute for anesthetics and medication.—*Editorial British M. J., Sept. 16, 1944*

Case Report

CONGENITAL MEGACOLON TREATED WITH MASSIVE DOSES OF SYNTROPAN*

VINCENT DEPAUL LARKIN, M.D., and ADOLPH G. DESANCTIS, M.D., New York City

THE use of syntropan in the medical management of certain cases of congenital megacolon was first suggested by Klingman.[1] In a search for a drug with the parasympathetic depressant action of atropine, but without its undesirable side-effects, he tried syntropan and reported excellent results in those cases characterized by spasm (achalasia) of the rectosigmoid apparatus. This group of patients exhibits failure of the rectosigmoid to relax, either as a result of overactivity of the sympathetics or failure of the parasympathetics to properly inhibit the normal activity of the sympathetics which innervate the rectosigmoid.

Case Report

Case 1.—W. V. S. (J61981), a 15-month-old white boy, was admitted the first time on October 13, 1941. Constipation and abdominal distention had been present since birth and pallor had been noted since the age of 1 month. Frequent administration of enemas and cathartics had always been required to maintain bowel function. An increase in pallor and progressive weakness were noted for the month prior to admission. The admission physical examination, including a rectal examination, was entirely negative, except for marked pallor and abdominal distention.

A blood count revealed marked anemia, with 1,600,000 red blood cells and 2.8 Gm. of hemoglobin, the white count and differential being within normal limits. The following tests were negative: Schick, Mantoux (1:1,000), blood Wassermann, erythrocyte sedimentation rate, and repeated urine analyses and stool examinations for ova and parasites. A blood chemical examination revealed an icterus index of 16.7 units and a positive indirect Van den Bergh test. Bile pigments were never found in the urine. A gastrointestinal series was also done during this first admission, the outstanding feature being a marked megacolon. X-rays of the long bones showed a moderate degree of decalcification.

The anemia quickly responded to transfusion and a course of prostigmine bromide orally (22.5 mg. in the morning and 15 mg. in the evening) established daily bowel movements, although no relief of the abdominal distention was obtained. One month after admission, daily bowel movements having been established for about a week, the patient was discharged. The improvement in symptoms was very brief, however, and a few days after discharge he was readmitted because of tremendous abdominal distention, obstinate constipation, and a temperature of 105 F., all of which responded promptly to a high colonic irrigation.

For two months following this second admission attempts were made to establish regular bowel movements by the use of prostigmine bromide and of mecholyl bromide (up to 250 mg. twice a day). A combination of 250 mg. of mecholyl bromide and 7.5 mg. of prostigmine bromide twice daily after meals produced typical symptoms of toxicity with no relief of the constipation.

Drug therapy of this type having failed, spinal anesthesia was resorted to in an attempt to evaluate the benefit which might be obtained from lumbar sympathectomy. Twenty-five mg. of procaine were injected into the spinal canal; the patient developed respiratory arrest and required artificial respiration, but no change in the size of the abdomen or spontaneous evacuation of the bowel was observed. This discouraged further investigation along these lines.

During the third month of hospitalization syntropan was started; 5 mg. were given three times daily and the patient responded immediately by moving his bowels once or twice a day and by a decrease in the abdominal distention. Doubling this dosage caused no further improvement and after one month of satisfactory bowel movements the child was discharged on this medication, plus a low residue diet and a dose of mineral oil every day.

For the next six months the patient did very well, moving his bowels daily, although during this period the dosage of syntropan had to be increased to 25 mg. three times a day in order to maintain a regular bowel function.

While still on this regimen constipation and dilatation of the abdomen recurred and the child was readmitted a third time. Syntropan was given in amounts of 100 mg. three times a day without effect and was then discontinued. Prostigmine and then mecholyl and the combination of the two were again tried unsuccessfully. Syntropan therapy was then resumed and with a dosage of 150 mg. three times a day there was moderate improvement. The dosage of syntropan was then slowly increased over a period of two months, in order to determine whether the patient would improve further with larger doses and to avoid, if possible, the periods during which he failed to respond to the drug. The dose finally reached 1,250 mg. daily in three divided doses. This large amount of syntropan was given daily for about three weeks, without evidence of toxicity but without further improvement in symptoms. For this reason the dose was decreased. The patient was discharged on April 21, 1943, on 100 mg. of syntropan three times daily and had satisfactory bowel movements for the next two months.

Discussion

Klingman[1] noted excellent results in his patients with doses of syntropan up to 150 mg. daily. Larger amounts were not given because the toxic levels were not known. The relative nontoxicity of syntropan, however, has been noted by other observers. Fromherz[2] declares that "the selective toxicity of atropine for the human central nervous system is

[Continued from page 310]

absent in syntropan." He noted that, in cat and rabbit experiments, the action of atropine was a thousand times that of syntropan in producing mydriasis, a hundred times that of syntropan in inhibiting salivation, five hundred times that of syntropan in its effect on the circulation, but only twenty times greater on nerve endings of isolated rabbit intestine. In other words, the action of syntropan approaches that of atropine on the smooth muscle of the intestine but is appreciably less in other effects. Clark[3] and his collaborators showed that syntropan in small amounts effectively antagonizes stimulation by drugs of the parasympathetic mechanism of excised intestine without muscular depression. Larger amounts of syntropan produce some direct muscular depression of excised intestine.

The largest doses of syntropan given to humans are reported by Schlezinger and Alpers[4] in the treatment of Parkinsonism in adults. The maximum dose administered was 3,200 mg. daily, with production of toxic symptoms. These included nausea, vomiting, palpitation, confusion, sluggishness, drowsiness, and visual hallucinations. They noted maximum improvement at a level of 2,400 mg. of syntropan daily, with no further improvement as the dose was increased.

The lack of toxicity of syntropan is well demonstrated in the present case. This patient, two years of age and weighing thirty pounds, received over 1,200 mg. of syntropan in divided doses daily for three weeks, without any evidence of toxicity. Obviously there is no cumulative effect, as evidenced by the long period in which the patient received the medication.

Review of the case reveals that no better results were obtained from a dosage of 1,250 mg. of syntropan daily than from the original dosage of 15 mg. daily. However, it was noted that the patient gradually required larger doses of the drug and that after his last discharge the maximum therapeutic effect was obtained with 100–300 mg. of syntropan daily.

Summary and Conclusions

A case of congenital megacolon which responded well to the use of syntropan is presented. The lack of toxicity, cumulative action, and side-effects of this drug are pointed out. Enormous doses may be given safely, but the maximum therapeutic effect is obtained with dosages far below the toxic level.

EYE EXERCISES FOR DEFECTIVE VISION

Revival of interest in the unorthodox methods of treating visual defects, the result of Mr. Aldous Huxley's *The Art of Seeing*, was discussed in the *Journal* June 31, 1943.[1] In his youth Mr. Huxley suffered an attack of keratitis punctata which left one eye just capable of light perception and the other with about 5 per cent of normal vision. After about a quarter of a century of struggling with increasing visual difficulties he met a woman disciple of the late Dr. Bates, and she initiated him into the regimen of "blinking," "winking," "nose reading," "palming," and "sunning." Within a couple of months, he reports, he had learned to read without the aid of artificial lenses and could also read without strain and fatigue, for he had learned to avoid the conditions making for strain and get rid of fatigue as soon as it began to manifest itself. Mr. Huxley believes that all defects of vision can be cured by induction of cerebral and ocular "dynamic relaxation."

Bate's hypothesis that visual derangements and refractive errors are due to a deformation of the eyeball, resulting from nervous and muscular strain of the superior and inferior oblique muscles, and that the ciliary muscle has nothing to do with the focusing of the eye, is contrary to well-established scientific and clinical observations. Huxley himself admits that his visual acuity has not improved. His point is that he has learned how to use what he has to better advantage. Lancaster, in a recent contribution, advances the thought that "buried in a mass of what to ophthalmologists seem foolish gestures and performances, best defined as hocus pocus, there are sound and fruitful ideas." He would remind the ophthalmologists that seeing is only half ocular; the other half is cerebral. Since seeing is only partly a matter of the image on the retina and the sensation it reproduces and is in still larger part a matter of the cerebral process of synthesis, in which memories play a principal role, it follows that by repetition, practice, and exercise one builds up a substratum of memories useful for the interpretation of sensations and facilitates syntheses which are the larger part of seeing.

This physiologic concept of the function of vision is not new. As Duke-Elder points out in his review of Huxley's book, visual defects are sometimes muscular in origin, sometimes psychologic. The competent ophthalmologist treats the former with curative exercises, while the latter requires the psychologic approach. Lancaster feels, however, that ophthalmologists have largely neglected this field and have concentrated their attention on the primary source of sensation, the image on the retina, leaving to irregular, half-trained workers the cultivation of what he considers a fruitful field of therapy.—*Editorial, J.A.M.A., Nov. 18, 1944*

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. *The members of the committee are Oliver W. H. Mitchell, M.D., Chairman, (428 Greenwood Place, Syracuse); George Baehr, M.D., and Charles D. Post, M.D.*

Cancer Teaching Day in Saratoga Springs

A TEACHING day on cancer was held at the Gideon Putnam Hotel, Saratoga Springs, on January 18. It was presented under the auspices of the Medical Society of the County of Saratoga, the Medical Society of the State of New York, and the New York State Department of Health, Division of Cancer Control.

The afternoon meeting was called to order at 3:30 P.M. by the chairman of the meeting, Dr. Frederick G. Eaton, president of the Medical Society of the County of Saratoga.

The first speaker, Dr. Andrew H. Dowdy, associate professor of radiology at the University of Rochester School of Medicine and Dentistry, Rochester, spoke on "Epithelioma of the Skin." Dr. Gray H. Twombly, assistant surgeon, Memorial Hospital, New York City delivered a lecture entitled "Cancer of the Cervix."

Dinner was served at 6:30 P.M.

The evening meeting at 8:00 P.M. was under the chairmanship of Dr. Joseph M. Lebowich, director of the Saratoga County Laboratory. The program consisted of two lectures: "The Significance of Enlarged Lymph Nodes," by Dr. Lloyd F. Craver, attending physician, Memorial Hospital, New York City, and "Diagnosis, Treatment, and Results in Cancer of the Breast," by Dr. Frank E. Adair, executive officer of Memorial Hospital, New York City.

Industrial Health

POSTGRADUATE instruction in industrial health was given before the Cortland County Medical Society on January 19 at 8:30 P.M., in the staff room of the Cortland County Hospital, Cortland.

A lecture, "Industrial Orthopaedic Problems," was given by Dr. Roscoe D. Severance, associate professor of orthopaedic surgery at the Syracuse University College of Medicine, Syracuse.

This instruction was presented as a cooperative endeavor between the Medical Society of the State of New York and the State Department of Health.

Psychiatry in General Practice

INSTRUCTION in psychiatry was given to the Jefferson County Medical Society in January 11 at 6:30 P.M., at the Black River Valley Club, Watertown.

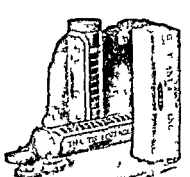
Dr. Samuel W. Hartwell, professor of psychiatry at the University of Buffalo School of Medicine, Buffalo, spoke on "The Recognition and Management of Psychiatric Problems in General Practice."

Postgraduate Series for Franklin County

POSTGRADUATE instruction has been arranged for the Franklin County Medical Society, to be held Tuesday evenings at 6 P.M. at the Elks' Club, Malone.

On January 16 Dr. Barton F. Hauenstein, assistant professor of medicine at the University of Buffalo School of Medicine, spoke on "Dysenteries—Bacillary and Amebic." On February 20 Dr. Frederick S. Wetherell, professor of clinical surgery at the Syracuse University College of Medicine, will speak on "Goiter—Its Management." On March 20 Dr. Leon H. Griggs, associate professor of clinical medicine at the Syracuse University College of Medicine, will discuss "Common Diseases of the Skin—Illustrated with Color Photography." On April 17 the lecture will be "Gynecology in General Practice," by Dr. Nathan P. Sears, professor of gynecology at the Syracuse University College of Medicine. On May 15 Dr. Ellery G. Allen, associate professor of clinical medicine and assistant professor of clinical pathology at the Syracuse University College of Medicine, will give a lecture entitled "General Résumé of Hematologic Disorders Including the Anemias."

This instruction is provided by the Medical Society of the State of New York, with the exception of the first and fourth lectures, which are provided by the Medical Society of the State of New York with the cooperation of the New York State Department of Health.

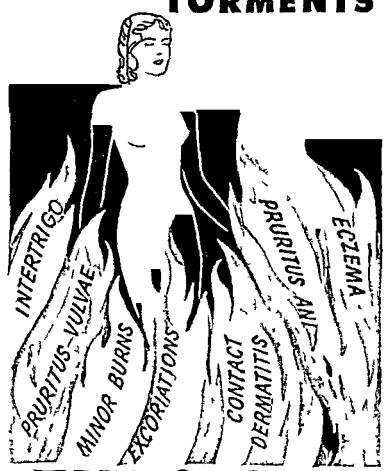


Thantis Season

Winter time is the season of throat affections Crowded transportation facilities, due to wartime conditions, cause exposure of more people to infection

Many physicians have found Thantis Lozenges to be effective in relieving throat soreness and irritation, because they are antiseptic and anesthetic for the mucous membranes of the throat and mouth.

Thantis Lozenges contain Merodicein (H W. & D Brand of Diiodooxymercuriresorcinsulfonphthalein-sodium), 1/8 grain, and Saligenin (Orthohydroxybenzylalcohol, H. W. & D), 1 grain They are effective and convenient, they dissolve slowly, permitting prolonged medication.



Thantis Lozenges are supplied in vials of twelve lozenges each.

County News

Albany County

Dr. Frank H. Lahey, director of the Lahey Clinic, Boston, was the speaker at the meeting of the county society on January 17. The title of his address was "Lesions of the Terminal Ileum, Colon, and Rectum."

Discussion of the paper was opened by Drs. J. Lewi Donhauser, Stanley E. Alderson, and Arthur M. Dickinson.

Broome County

At the annual meeting and election of officers of the Broome County Medical Society held December 12, 1944, the following officers were elected for the year 1945: president, Dr. Frank G. Moore, Endicott; vice-president, Dr. Victor W. Bergstrom, Binghamton; secretary, Dr. J. C. Zillhardt, Binghamton; assistant secretary, Dr. Alfred L. Standfast, Binghamton; treasurer, Dr. Leonard J. Flanagan, [illegible] assistant treasurer, Dr. John M. [illegible] chairmen of committees: legislative, Dr. Elton R. Dickson, Binghamton; economics, Dr. Richard W. Rice, Johnson City; public relations, Dr. Charles M. Allaben, Binghamton; public health, Dr. Ralph M. Vincent, Binghamton; milk commission, Dr. Perry H. Shaw, Binghamton; library, Dr. Stuart B. Blakely, Binghamton; membership, Dr. Ralph J. McMahon, Binghamton; Compensation Board (for term of three years): Dr. Myer S. Bloom, Binghamton; Dr. Harry I. Johnston, Binghamton; Dr. Silas D. Molyneaux, Binghamton; board of censors: Dr. Charles M. Allaben, Binghamton; Dr. Stuart B. Blakely, Binghamton; Dr. Howard W. Davis, Binghamton; Dr. Harry I. Johnston, Binghamton; Dr. Edward M. Jones, Endicott; delegates to the State Society: Dr. Victor W. Bergstrom, Binghamton; Dr. Harry I. Johnston, Binghamton; alternate delegates: Dr. Elton R. Dickson, Binghamton; Dr. George C. Vogt, Binghamton.

Fulton County

Dr. Richard B. Cattell, assistant to Dr. Frank H. Lahey of the Lahey Clinic in Boston, was guest speaker at the regular meeting of the county society held in Gloversville on December 13. Dr. Morris Kennedy, president, presided.

The subject of Dr. Cattell's talk was "Recent Progress in Biliary Tract Surgery."

This was the fourth time during the past year that the society had as guest speakers famous men in the world of medicine and surgery.

About thirty members attended the meeting, and there were also a number of visiting physicians from Montgomery County in attendance.*

Kings County

The forty-seventh annual meeting of the Associated Physicians of Long Island was held at St. John's Hospital, Brooklyn, on Saturday, January 27.

The morning program consisted of clinics. The scientific session, at 2:30 P.M., was devoted to six ten-minute papers with discussions on diversified subjects. The annual dinner was served at 6:30 P.M. at the Brooklyn Club.

Nassau County

The appointment of Dr. Joseph H. Kinnaman, of Malverne, to the post of Nassau County Deputy Commissioner of Public Health by the Board of Health has been announced by Commissioner Dr. Earle G. Brown. Dr. Kinnaman was the director of the Kay County Health Department of Oklahoma and is the former director of the City of New Rochelle's Health Department. His appointment has the approval of the Nassau County Medical Society. He fills the position which has been vacant since the retirement of Dr. William H. Runcie, of Freeport, last April.

Dr. Kinnaman left New York in 1942 to take charge of a demonstration unit in Oklahoma, sponsored by the Commonwealth Fund of New York City.

A native of the State of Iowa, Dr. Kinnaman was graduated from the State University, having received his Bachelor of Science degree cum laude. He received the Doctor of Medicine in 1925. Following two years of teaching at the University of Iowa, he engaged in full-time public health activities as a deputy commissioner in Cleveland and Peoria. He was director of the Division of Maternal and Child Health in the Iowa State Department of Health for six years. Dr. Kinnaman took postgraduate work at Johns Hopkins University School of Public Health, receiving his degree of Master of Public Health in 1938.

He is a member of the Oklahoma State Medical Society and the American Medical Association. He has served as Director of Public Relations for Kay County Medical Society and was secretary of the medical staff of Ponca City Hospital. He is a Fellow of the American Public Health Association and chairman of the Health Officers' Section.*

Monroe County

Dr. Sidney C. Madden, associate professor of pathology, University of Rochester School of Medicine and Dentistry, has accepted a position as professor of pathology and head of the department of pathology at Emory University School of Medicine, Atlanta. The appointment will be effective in March.

Dr. Madden fills the vacancy which occurred when Dr. Roy R. Kracke left Emory to become dean of the University of Alabama School of Medicine, Birmingham.

New York County

Dr. Bret Ratner addressed the students of the Medical College of the University of Pennsylvania on January 12 on the subject "The Nature of Allergy."

Oneida County

At the December meeting of the Utica Academy of Medicine the speaker was Maj. Thomas A. Johnson of Rhoads General Hospital, Utica. The title of his paper was "The Irritable Colon." Discussion

Comfort during Coryza

In addition to bed rest, anti-pyretics and other general measures, a few drops of Sulmefrin bring quick comfort. The danger of sinusitis and other complications is lessened. Sulmefrin is a decongesting preparation containing sulfathiazole. Its mildly alkaline vehicle helps to dissolve mucous and mucopurulent secretions. It produces effective shrinkage of swollen nasal mucosa without the undesirable reactions accompanying excessive vasoconstriction.

Sulmefrin is a stabilized aqueous solution of an effective vasoconstrictor—*dl*-desoxyephedrine hydrochloride (0.125%) —plus sulfathiazole sodium (2.5%). Administered by spray, drops or tamponage.

Sulmefrin
TRADEMARK

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

[Continued from page 316]

was opened by Dr. F. M. Miller, Jr. The second speaker was Lt. Comdr. William Wallace, who related his experiences "With the Sea Bees at Attu."

Major Johnson is professor of gastroenterology in the Graduate School of Medicine at the University of Pennsylvania and is a member of the staffs of several Philadelphia hospitals. Lt. Comdr. Wallace recently returned from Attu in the Aleutians where he served as chief medical officer in the Naval Hospital there.

Dinner was served preceding the meeting.

• • •

The annual meeting of the county society took place on January 9 at the Hotel Utica. Dr. F. M. Miller, Jr., gave the president's address and election of officers was held. The list of the new officials will appear in a later issue.

A dinner was given at 7:00 P.M. before the meeting.

Ontario County

The first quarterly meeting of the county society for 1945 was held in Canandaigua at the Canandaigua Hotel on January 9. Following dinner and business meeting, Dr. Earle B. Mahoney, assistant professor of surgery at the University of Rochester, read a paper entitled "Chest Surgery."

Suffolk County

Sponsored by the medical board of the Huntington Hospital, a series of lectures on important and timely medical subjects has been planned for the general public. There is no admission charge.

The committee on arrangements for this course consists of Dr. Burdge P. MacLean, of Huntington, chairman; Dr. Anthony Cherry, of Huntington Station; Dr. Max Kimbrig, of Huntington; and Dr. Walter Novotny, of Northport.*

Westchester County

A regular meeting of the county society was held on January 16 at 8:30 P.M. at the New York Hospital, Westchester Division, White Plains. Two addresses comprised the scientific program: "The Medical Approach to Psychosomatic Problems," by Dr. James Flexner, and "The Psychiatric Approach to Psychosomatic Problems," by Dr. James H. Wall.

• • •

Dr. Joseph H. Beattie, dean of the practicing physicians in the Town of Greenburgh, was honored on December 6 at a dinner party in the Sleepy Hollow Country Club given by the medical staff of the Dobbs Ferry Hospital, of which he is a past president.

The dinner celebrated forty years' practice in this area by Dr. Beattie. He was presented with a gift from his colleagues by Dr. Harold A. Storms. He was extolled for his service to the community, charity, and interest in the welfare and growth of Dobbs Ferry by Dr. E. F. Sands, president of the medical staff, and others.

A native of Warwick, New York, Dr. Beattie attended Warwick Institute before entering the New York Homeopathic Medical College, from which he was graduated in 1902. For two years he interned at the Hahnemann Hospital in Philadelphia and spent a summer season in postgraduate work in London, England, before beginning his professional career in Dobbs Ferry in 1904.

Dr. Beattie enlisted in the Army on June 13, 1917, was commissioned a first lieutenant, and advanced to the rank of major in the expeditionary force in France.

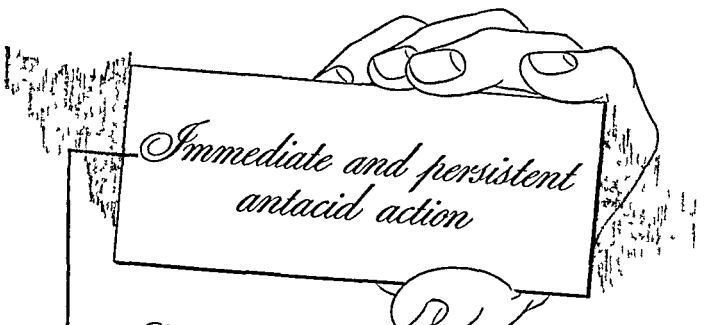
Dr. Beattie is affiliated with the American Medical Association, State Medical Society, Westchester Medical Society, Association of Military Surgeons, Veterans of Foreign Wars, and the American Legion. He has been a benefactor for many years of the Dobbs Ferry Free Library, where a memorial shelf is maintained in memory of his wife, Annie M. Baxter Beattie.*

• • •

The Westchester Medical Society's governing board has authorized its war participation committee, headed by Dr. E. Leslie Burwell, of New Rochelle, to set up a panel of county doctors to treat World War II veterans. The Veteran's Information and Service Center called the society's attention to this urgent need for returning servicemen and -women.

At an executive session, the war participation committee was requested to arrange for panel personnel from the various county areas and to formulate a program to provide necessary medical examination, care, or advice for veterans, Boyden Roseberry, executive secretary of the Medical Society, said. Dr. William A. Holla, county health official, has indicated that public health clinics are expected to care adequately for the present small volume of veterans until the medical panel is established.

The number of doctors on the panel is expected to vary with the magnitude of the work, Mr. Roseberry said. Some of the society members are veterans of World War I, but all members are anxious to cooperate in any possible way, he also stated. The workers are volunteers.



Facilities and personnel for handling psychiatric and malaria cases are inadequate for any large volume at present, but the medical society will make long-range plans to provide the most adequate possible service.*

PHYSICAL THERAPY COURSES AT COLUMBIA

During the winter and spring sessions, 1944–1945, Columbia University will give a ten-month course leading to a Certificate of Proficiency for Technicians in Physical Therapy.

Admission to the course will be granted to qualified students aged 19 to 35 years who have graduated from an approved high school and can satisfy one of the following requirements: (*a*) two years of acceptable college work, including courses in biology and other sciences, physics and chemistry recommended, or (*b*) graduation from an accredited school for nursing, or (*c*) graduation from an accredited school of physical education.

For further information and application forms, prospective students should apply to the Director of University Admissions, Room 321, University Hall, Columbia University, Morningside Heights, New York 27, New York.

Creamalin promptly reduces acidity within the stomach. The antacid effect is persistent. There is no local compensatory reaction, such as commonly occurs with alkalies, and hence no belated oversecretion of hydrochloric acid Moreover, there is no risk of producing alkalosis.

Creamalin promptly relieves pain and heartburn associated with gastric hyperacidity

Creamalin often induces healing of peptic ulcer when employed with an ulcer regimen.

College of Surgeons Announces Hospitals Approved for Graduate Training in Surgery

THE American College of Surgeons announces that two hundred and thirty-one hospitals in the United States and Canada have been approved for graduate training in general surgery and the surgical specialties. The list of approved hospitals for this purpose is published in the annual Approval Number of the *Bulletin* of the College just issued. As a result of the 1944 survey, nine additions to the approved list were made compared with last year.

In announcing the new approved list, Dr. Malcolm T. MacEachern, associate director, states that five hundred or more surveys of hospitals offering opportunities for graduate training in surgery are planned during the coming year, the increased emphasis upon this work being stimulated by the need for providing ample opportunities for resumption of training by medical officers when they return from service with the armed forces. The College, through Maj. Gen. Charles R. Reynolds, Consultant in Graduate Training in Surgery, Dr. George H. Miller, Director of Educational Activities, Dr. Paul S. Ferguson, Director of Surveys, and a field staff, helps hospitals to organize graduate training programs to meet the requirements for approval, and also plans to aid physicians returning from service in resuming their training in surgery.

The New York State approved hospitals are:

Albany Hospital, Albany; Brooklyn Eye and Ear Hospital, Cumberland Hospital, House of St. Giles the Cripple, Jewish Hospital, Kings County Hospital, Long Island College and Kings County Division, Long Island College Hospital, and St. John's Hospital, Brooklyn; Buffalo General Hospital, Edward J. Meyer Memorial Hospital, and Millard Fillmore Hospital, Buffalo; Clifton Springs Sanitarium and Clinic, Clifton Springs; Queens General Hospital, Jamaica; Babies' Hospital, Bellevue Hospital, Beth Israel, Flower and Fifth Avenue Hospitals, Goldwater Memorial Hospital, Harlem Eye and Ear Hospital, Hospital for Joint Diseases, Hospital for Special Surgery, Lenox Hill Hospital, Manhattan Eye, Ear, Nose and Throat Hospital, Memorial Hospital for the Treatment of Cancer and Allied Diseases, Metropolitan Hospital, Mount Sinai Hospital, Neurological Institute, New York Eye and Ear Infirmary, New York Hospital, New York Orthopaedic Dispensary and Hospital, New York Post-Graduate Medical School and Hospital, Presbyterian Hospital, St. Luke's Hospital, Sloane Hospital for Women, and Women's Hospital, New York City; Rochester General Hospital, Rochester Municipal Hospital, and Strong Memorial Hospital, Rochester; Grasslands Hospital, Valhalla; and Sea View Hospital, West New Brighton, Staten Island.

LaGuardia Outlines Postwar Hospital Expansion in New York City

MAYOR F. H. LaGuardia announced on November 8 that his postwar blueprint for New York envisages the construction of five new hospitals, the complete remodeling of a sixth, the expansion of present medical research facilities, and the creation of a forensic medical institute.

The Mayor told several hundred registered nurses attending a meeting of the Thirteenth District of the New York State Nurses Association, that New York's twenty-six institutions with 20,000 beds already constituted "the greatest hospital system in the world."

He added:

"When our plans are completed no one will be able to dispute our supremacy in medical education and treatment."

These plans include a large hospital in the Bronx to replace Fordham Hospital, a new hospital in Harlem, a hospital for tropical diseases which will form part of the program to extend the facilities of existing medical research institutes; a custodial hospital for incurable cancer patients to be affiliated with Memorial Hospital, and the completion of Florence Nightingale Hospital for cancer patients, which was interrupted by the war after the foundation had been laid and which "will be a scientific institute connected with Columbia University."

In addition, the Mayor planned "to rebuild entirely Sea View Hospital," at West New Brighton, Staten Island, and "to provide a forensic medical institute to be constructed near Bellevue Hospital."

"This is quite an ambitious program," Mayor LaGuardia remarked, "but I am going to press it and give it a very high priority in our postwar program."

Noting that these new hospitals would create new demands for medical personnel, Mayor LaGuardia expressed confidence that this program, together with his health insurance program, would enable New York to absorb all medical war veterans returning to this area.

Improvements

Mason General Hospital, Brentwood, has opened Edgewood as an annex, increasing the capacity of the hospital, already the Army's largest for the treatment of nervous and mentally ill members of the Army, to more than 3,000 beds. The Edgewood annex consists of seven buildings located on a site of 50 acres, approximately three miles from Brentwood, and two miles from Mason.

Edgewood, like the original buildings at Mason, was constructed by the State of New York, but was not occupied until leased by the Army. The entire construction, including changes now in progress necessary for Army use, and its equipment, has cost approximately $9,500,000. The government's lease on these buildings for hospital use is for the duration of the war.

This annex, which in its main building is thirteen stories high, of fireproof construction, has 700,000 square feet of floor space. It has thirty wards, and a recreation room, kitchen, and mess hall on each

IODINE...

Logical Leadership

In view of Iodine's efficiency demonstrated through in vitro and in vivo tests; in view of its combined bacteriostatic and bactericidal action; and in view of its lasting effectiveness, it is logical that Iodine has remained an antiseptic of choice through the years.

It is a preferred germicide in pre-operative skin disinfection and in the treatment of wounds, cuts and abrasions Its rapid and trustworthy action justifies the reliance which the profession places upon it.

floor. There is also a central kitchen with connecting mess halls for post personnel.

The staff, under the direction of Col. Cleve C. Odom, commanding officer, is engaged in setting up in the new building all the offices, laboratory, and treatment facilities needed for the care of patients who are returned from the various battle areas. Occupational therapy shops, physical therapy and hydrotherapy rooms have been set up, and a recreation hall and gymnasium are under construction.

All of the advanced reconditioning activities will be housed in the Edgewood annex, including a complete physical education and educational program, and occupational therapy work.*

• • •

As a result of the initiative of Harold C. Welch, business manager of the Onondaga County Tuberculosis Sanatorium, bus service to and from that institution will now be available to people who do not own motor cars. That is a fine achievement. Many parents and friends of patients who have not been able to visit them because of a lack of transportation will now find it possible to see them regularly.

Incidentally, Mr. Welch deserves credit for another beneficent development in connection with the Sanatorium. The Free Treatment Bill which he pushed at Albany has now been written into the statutes. As a result people of limited means can be treated at the Sanatorium with remuneration to the county arranged on the basis of their ability to pay. This is an important forward step, as it makes possible the effective treatment of many for whom there would otherwise probably be little hope.*

• • •

For those whose 1945 destiny entails a stay in Meyer Memorial Hospital, here is a note of cheer: They will find it a vastly pleasanter place than it has been this year.

The improvement program launched there is a comprehensive one, and probably won't be completed until June.

Arrangements have been made to clean the windows once every three months.

The walls are being washed and repainted. In the Communicable Disease Building the walls of the corridors and the rooms are bright with two new colors, some a light brown and buff above and others aquamarine below and buff above. Flowered drapes frame the windows and the patient's lot is made easier by beds which can be adjusted for those able to sit up. The old beds were nonadjustable. The mattresses are new and thick.

In the Children's Building the painting is still in progress, but the new cribs and mattresses have been installed.

The pendant lights are being replaced throughout the hospital with the adjustable, shaded sort. New bedside tables are now being selected and stainless steel equipment will soon be available for all floors.

Down in the kitchen, new ovens, steamers, boilers, and the like were installed and were ready as soon as a transformer arrived late in December. The old food carts are being replaced by electric food carts which will keep the food hot all the way.

New furniture will be ordered for the ward porches, new tables and chairs for the ward dining rooms, and new bedside chairs. Even the hot and cold water faucets are being replaced, at a cost of $7,000.

New linoleum will replace the old, decayed floor covering, the elevator and lighting systems are being modernized, and the fire escapes and balconies repaired. Of the $300,000 allocation, $204,704 has been spent or accounted for by orders and contracts thus far*.

• • •

Capacity of the United States Veterans' Facility at Batavia will be doubled under postwar plans that have been made and $480,000 has been approved by the Appropriations committee of the House of Representatives.

The expansion program will not be started until the end of hostilities, because of the lack of nurses which at present is preventing full use of the present hospital, it was officially announced. The plans provide for additions which will provide a 700-bed facility, it was said.

• • •

Through the generosity of an anonymous friend the Champlain Valley Hospital has acquired a Davidson incubator for the maternity department.

The incubator is said to be the first of its kind manufactured since 1941, and only through an urgent necessity was a priority available. Believed to be the only one of its kind in Northern New York, it has been instrumental as an aid in establishing what is understood to be a world record in raising premature children. At the Lying-In Hospital of the Cornell Medical Center, they raised one infant weighing 17¼ ounces at birth. After forty-one days the baby developed into a normal healthy child. Bellevue Hospital in New York City raised a 19½ ounce infant who spent three months in the incubator. Misericordia Hospital in New York raised triplets whose combined weight was less than eight pounds. They were in the incubator sixty days.

To quote the hospital authorities in Plattsburg, the new incubator is almost human, its mechanics being automatic, yet requiring the presence of an attendant nurse to manipulate the various switches. It is practical to conduct a thorough physical examination of the child while the infant remains inside the incubator. Isolation from sudden temperature changes and protection from air-borne bacteria, both of prime importance in the care of the premature baby, are made possible.

Atmosphere and temperature are regulated to meet requirements in separate cases by thermostatic controls. Being 100 per cent automatic and having every safeguard provided, the machine is so simple that anyone can understand and learn to operate it in a few minutes. There is little for the attendant nurse to do except add water daily and see that some ice is in the ice compartment, if oxygen is being used.

At the Helm

Lewis W. Douglas, president of the Mutual Life Insurance Company of New York, was elected chairman of the board of managers of Memorial Hospital, New York City, at the regular monthly meeting on December 19, it was announced by Harry Pelham

CONFORMAL Personalized SHOES FOR MEN AND WOMEN

MOULDED TO YOUR ARCHES

Accepted for advertising by the Journal of the American Medical Association

At last!

DOCTORS' DREAM OF WHAT A CORRECTIVE SHOE SHOULD BE

Your prescription filled to exact specifications

The Conformal feature—the built-in plastic arch—eliminates all guesswork. The correction is actually made *on the foot*, while the shoe is being moulded to conform to the requirements of each individual foot.

Your patients satisfied as never before

Conformal Shoes keep the feet *looking*, as well as feeling, ship-shape. Wearers actually forget they have on corrective shoes!

Body weight forces softened plastic away from ball and heel, UP under arches where it solidifies.

Robbins, president. Mr. Douglas, seventh member of his family to be connected with the hospital, succeeds his uncle, the late Archibald Douglas, who died in December, 1943.

The interest of the Douglas family in the hospital began in 1912 when Dr. James Douglas, grandfather of the new chairman of the board of managers, became a member of the board and gave $100,000 for clinical research and an x-ray plant. The new chairman is also a trustee of the General Education Board, the Rockefeller Foundation, and the National Industrial Conference Board, Inc.*

Dr. Francis C. Shaw, now assistant superintendent of Matteawan State Hospital, has been appointed superintendent of Dannemora State Hospital, Dr. John F. McNeil, Matteawan superintendent, has made known.

Dr. McNeil said the appointment was made on November 24 by the State Department of Correction and that Dr. Shaw assumed his duties at Dannemora on December 1.

Naming of a successor to Dr. Shaw as assistant superintendent at Matteawan will await the compiling of a Civil Service list of eligible persons, Dr. McNeil said.

Dr. Shaw succeeds Dr. Blakely R. Webster, who is retiring, as superintendent at Dannemora State Hospital.

Dr. Shaw was appointed to Matteawan as a clinical director in April, 1929. He was advanced to first assistant physician in April, 1931, and he was appointed assistant superintendent at Matteawan in April, 1940.

On November 27 in the attendant's dining room of the Dannemora State Hospital, a testimonial buffet supper was served in honor of Dr. Webster's retirement as director of the institution. An overcapacity group of hospital employees attended.

Dr. Harold E. Connelly, assistant director, was master of ceremonies. He paid tribute to Dr. Webster in an address and presented him with a gift as a token of appreciation

After the gift presentation, Arthur S. Lefeve, senior business assistant to the director, Ralph E. Walker, president of the State Hospital chapter of the Association of State Civil Service Employees of the State of New York, and Thomas J. Devlin, chief attendant, also paid tribute to Dr. Webster.

Dr. Webster graduated from Cornell University Medical College in 1907 and interned at the New York City Hospital (1907–1909), and then took up private practice (1909–1912) in Blairstown, New Jersey, and Pine Bush, New York. He served the State at Matteawan as junior, senior, and temporary first assistant physician. He was appointed first assistant physician at the Dannemora State Hospital, and resigned September 25, 1921, for a position with the Veterans' Administration Facility, New York. He returned to Dannemora (reinstatement) April 28, 1922, and was appointed to the position of superintendent in February, 1935, which title was changed to director on April 1, 1944.*

• • •

Dr. Raymond Maslyn, a graduate of Albany Medical College, has reported for duty as resident physician in medicine and surgery at Ellis Hospital, it was announced by Miss Mary G. McPherson, hospital administrator.

Dr. Maslyn externed at Troy and Albany hospitals and interned at Rochester General Hospital. He has had three years' experience as an assistant biochemist and bacteriologist at Clifton Springs.*

• • •

Dr. Curtis J. Becker, of St. George, who is on the medical staffs of Staten Island Hospital and the Metropolitan Life Insurance Company, has been appointed one of the medical directors of Wagner College, it was announced by Clarence C. Stoughton, president of the college.*

• • •

Members of the Board of Supervisors were asked to authorize the appointment of Supervisor W. Vincent Grady, Beacon, and Harold S. Wright, Clinton, to a special committee to study the possibility of providing communicable disease hospital facilities in Dutchess County, Leonard J. Supple, board chairman, said.

If board approval is given the two supervisors will serve on a committee composed of four members of the Dutchess County Medical Society and two members of the Poughkeepsie Board of Aldermen.

Representatives of the Medical Society on the Committee are Dr. Scott Lord Smith and Dr. James E. McCambridge, both of Poughkeepsie; Dr. Edgar F. Powell, Fishkill; and Dr. L. Edward Cotter, Red Hook. Aldermen Kirchner and Robertson have been named to represent the city on the committee.

Supervisor Supple said he would present the names of Supervisors Wright and Grady to the board for approval at the December 19 meeting.

• • •

William J. Herron and George Frechette were elected to the board of directors of the Alice Hyde Hospital, Malone, at its annual meeting on December 11.

Mr. Herron succeeds H. B. Kelley, who resigned last April to accept appointment as assistant treasurer, in charge of financial matters at the hospital. Mr. Herron's term expires in 1948.

Mr. Frechette succeeds Alfred Brooks, resigned. Mr. Frechette's term expires in 1945.

Dr. P. F. Dalphin, Dr. A. L. Rust, and George B. Bradish, whose terms have expired, were reelected.

George J. Moore was chairman of the nominating committee, of which T. J. McKee and Dr. Joseph Wilson also were members.

Another nominating committee composed of Heyward Irving, D. N. Callander, and E. J. Van Deusen, was appointed to choose a slate to fill vacancies on the executive board. A. W. Hyde and T. J. McKee were elected to succeed themselves. Mr. Herron was named to succeed Mr. Bradish, whose term expired; Mr. Frechette to succeed Mr. Brooks and Paul Cantwell to succeed A. I. Marshall, resigned.

The executive board met at the close of the meeting of the large board and elected the following officers: president, D. N. Callander, vice-president, E. J. Van Deusen, secretary, George Frechette, and treasurer, T. J. McKee. Mr. McKee served as treasurer during the past year and was re-elected. The nominating committee was composed of A. W. Hyde, Dr. Joseph Wilson, and Heyward Irving.*

Martin H. Wright, of Perry, has been renamed president of the Board of Managers of the Wyoming County Community Hospital in Warsaw. Wright's election to that post was made at a Board meeting on December 6 at the hospital.

Wright became a member of the hospital board in 1930, when the hospital ceased functioning as a private enterprise and came under county-state responsibility. His present term expires in 1948. Harry Brown, of Warsaw, and Wright are the only two original appointed members remaining on the board.

Other officers named are: Dr. L. C. Sierk, of Attica, vice-president, and Harry M. Brown, of Warsaw, secretary.

• • •

Dr. J. A. Gindling was elected president of the Medical Staff of the Geneva General Hospital at the annual staff dinner meeting December 7 at the Belhurst Club.

Dr. Henry Abbott gave a talk at the meeting on contact lenses.

• • •

The resignation of Miss Janet M. Ptolemy, night superintendent of Ellis Hospital, was accepted "with regret" by hospital authorities as of December 1, it was announced on December 7 by Miss Mary G. McPherson, administrator at Ellis.

Miss Ptolemy, a graduate of the Roosevelt Hospital School of Nursing, New York City, will become superintendent of Sharon Hospital, Sharon, Connecticut. She came to Schenectady from Oberlin College, Oberlin, Ohio, where she had served as superintendent of Alden Hospital fourteen years.

Miss Ptolemy will be succeeded by Mrs. Ruth Ingalls, former assistant orthopaedic supervisor at the hospital and a graduate of the Schenectady Hospital Association's School of Nursing at Ellis.

• • •

Dr. A. J. Roach, for the past twelve years superintendent of the Broome County Tuberculosis Hospital, took over the duties of superintendent of the Montgomery Sanatorium on Swart Hill December 1. Dr. Roach is well qualified to serve in this administrative capacity, having had a wide experience in New York, Massachusetts, and Wisconsin.

• • •

Further action on plans to erect a general hospital in Schenectady to be operated by a community of Catholic Sisters has been referred to an executive committee appointed by Most Rev. Edmund F. Gibbons, bishop of the Catholic diocese of Albany. The members of the committee are:

Rev. Michael A. Bianco, pastor of St. Anthony's Church; Rev. Ladislaus E. Guzielek, pastor of St. Adalbert's Church; Very Rev. John J. Finn, VF, pastor of St. Helen's Church; Rev. Francis S. Ren, pastor of St. Mary's Church; Rev. Maxine E. Sarrault, pastor of Sacred Heart Church; Rev. William C. Keane, pastor of St. Luke's Church; Rev. Alphonse Orvidas, pastor of Holy Cross Church; Rev. Florian C. Billy, OMC, pastor of Sts. Cyril and Method Church; Rev. Leo B. Schmidt, pastor of St. Joseph's church; Rev. Edwin Wattson, pastor of St. Joseph's Church, Scotia.

Father Finn has been appointed chairman of this committee, Father Keane is secretary, and the treasurer is Father Schmidt.

• • •

A communication from Dr. Lawrence J. Early, as secretary-treasurer of the Columbia County Medical Society, recommending the names of three county physicians, from which list the Board of Supervisors will appoint one to serve on the Columbia County Board of Health, was referred to the committee after it was read at a meeting of the Supervisors.

Dr. Early's letter stated:

"In accordance with a request of Dr. Cecil L. Schultz, president of the Columbia County Medical Society, I am sending you the names of Dr. F. C Maxon, of Chatham, Dr. Hugh G. Henry, of Germantown, and Dr. C. L. Nichols, of Philmont, for your consideration in appointing a member to fill the vacancy now existing in the Board of Health."

• • •

Miss Thelma Ward, the new superintendent of the Peekskill Hospital, started her duties on December 12 at the hospital, in place of Miss Helen McClymonds, who recently retired because of ill health.

Mrs. Richard Donnelly, assistant superintendent; has been on the job now for several weeks, replacing Miss Ivers, who had resigned to accept a position at Mount Florence.

Miss Ward has had eighteen years' experience, much of it in a supervisory capacity, before coming here.

Miss Ward was graduated from the University of Cincinnati, Ohio. She then entered training in Cincinnati General Hospital, rising to the position of assistant night supervisor of the 1,000-bed hospital.

She then became superintendent of the Harlan (Kentucky) Hospital; superintendent of Woodlawn Hospital at Morberly, Missouri; superintendent of Stephens Clinic Hospital, Welsch, West Virginia; superintendent of Hillcrest Hospital, Pittsfield, Massachusetts; superintendent of nurses at Belmont Hospital, Worcester, Massachusetts; superintendent of Dodge County Hospital, Fremont, Nebraska, and superintendent of St. Peter's Hospital, Helena, Montana.

Miss Ward left a position as director of the 100-bed Portsmouth (Ohio) General Hospital to come to Peekskill.

Miss Ward was selected by the board of directors of Peekskill Hospital after the board had conferred with her and had examined applications from twenty-five others.

Another change in the hospital administration is that Dr. Frank J. Peroni, recently of New Rochelle, has been engaged as house physician, succeeding Dr. Edward Komando, who has gone to Rockland, Massachusetts.*

Newsy Notes

Little Falls chapter of the American Red Cross is organizing a camp and hospital council, headed by Theodore Lyons, former chapter chairman. Rev. J. Harold Thomson is vice-chairman of the council.

The purpose of the new organization is to assist in securing recreational equipment for service camps and government hospitals and to advise local groups

SYMPOSIUM ON INDUSTRIAL MEDICINE

For Physicians in Industry and Public Health

Five Days—April 2 to 6, 1945

This symposium consists of lectures, demonstrations and practical discussions. The subjects considered include pre-employment examinations, psychiatric problems in industry, the control and treatment of respiratory infections, detection of tuberculosis, the cause and remedy of absenteeism, vascular diseases and their treatment, industrial dermatoses, traumatic surgery, dust hazards, metal poisonings, newer methods in physiotherapy, the special problems of women in industry, and the use of penicillin in industry. Fee, $45.

and individuals concerning the needs of the institutions and the regulations governing gifts. At present the council is acting on requests from Rhoads Hospital at Utica.

Those who wish to give articles to the patients of this hospital should consult either the chairman or vice-chairman of the council. The committee will also give assistance in packing and delivering articles and will furnish letters of introduction to those who wish to take gifts to Rhoads. Articles will be forwarded in the name of the donor.

Chairman Lyons said today that the committee will be kept informed by the hospital as to articles needed by patients. The following is a list of those which will be most useful at Rhoads at the present time:

Cigarettes, cigars, shaving kits, khaki socks and knitted gloves, white linen handkerchiefs, small picture frames, writing kits, mechanical pencils, radios, recording machine, afghans, ditty bags, cast socks, sweaters. No home-made candies or cookies can be accepted.*

The medical staff of Veterans' Memorial Hospital of Ellenville sponsored a meeting for physicians, dentists, nurses, and pharmacists of the area at the Wayside Inn on December 5. Dr. R. C. Arnold, surgeon of the U. S. Public Health Service and director of the venereal disease research laboratory of the U.S. Marine Hospital at Staten Island, gave a very interesting talk on penicillin therapy in venereal diseases as well as in other diseases. The lecture was provided by the Council Committee of Public Health and Education of the Medical Society of the State of New York. Following the meeting movie shorts on popular health topics were shown and refreshments were served. Dr. John Weiss acted as chairman and made the arrangements for the program.

* * *

Preliminary plans for the construction of the proposed Columbia Memorial Hospital were disclosed on December 11 by L. P. Hover, Superintendent of Highways and member of the Building Committee authorized by the Board of Trustees of Hudson City Hospital to undertake all details of financing and building, at a meeting of the Rotary Club at the General Worth Hotel. The new hospital, Mr. Hover said, which has been conceived as a memorial to those who have served in all the wars of the country, will occupy a site on the grounds of the present Hudson City Hospital, which it will replace.

"There is no question of the need for the new hospital," the speaker declared. "In recent years, the Hudson City Hospital has been forced to operate far beyond practical capacity, as the result of the steadily increasing demands for its services. The record shows that more than 4,000 persons were served by this hospital during the past year. It is a matter of vital concern to every public-spirited citizen that there be provided modern, efficient health protection commensurate with the needs of our families and children."

To finance the building of the new hospital, which will cost approximately $1,250,000, a public appeal for funds will be made sometime in 1945. It is expected that considerable industrial and business support will be forthcoming.

Expressing the hope that citizens of Columbia County will consider the new hospital not the project of the Building Committee alone, but a postwar plan of prime concern to their own welfare, Mr. Hover concluded by characterizing the hospital as "Columbia's strategic medical center for the service of all."

Members of the Building Committee include Herman F. Zorn, chairman; William H. Graves, president of the Board of Trustees of the Hudson City Hospital; Mrs. George C. Inman, secretary; J. Wessel Ten Broeck, treasurer; James E. Leath, chairman of publicity; Dr. B. Caldwell Esselstyn, staff representative; Mrs. John S. Williams, co-chairman of solicitations outside Columbia County; L. Proseus Hover, chairman of solicitations in Hudson and Columbia County; Dr. R. P. Harris, chief of staff of the Hudson City Hospital, and Dr. John L. Edwards, staff representative.*

* * *

More than a majority of the thirty-eight attending and consulting members of the staff of General Hospital, Utica, on December 12 went on record in opposition to closing the hospital and urged its continuance.

Dr. Gordon A. Holden, retiring president of the staff, said the staff members were of the opinion that the burden of hospital beds in private hospitals were such that they could see no possibility for the care of the poor in other hospitals.

Dr. A. R. Hatfield, Jr., was elected president of the staff at the annual meeting, succeeding Dr. Holden. Others elected were: vice-president, Dr. A. Graham Davis; secretary-treasurer, Dr. Robert J. MacCallum.*

* * *

The Pierce Creek 4-H Club sang Christmas carols to children confined in Triple Cities hospitals as a part of the organization's singing project.*

* * *

The endorsement by heads of the Ossining War Council and the men's and women's veteran organizations of Ossining of the suggestion made by Timothy F. Walsh that Croton Point be selected as the site for a rehabilitation hospital for sick and wounded U.S. servicemen, is now under consideration by Brigadier-General Frank T. Hines, chairman, Federal Board of Hospitalization, Washington, D.C.*

* * *

Total expenditures for the year at the Oswego County Sanatorium for care and treatment of tuberculosis patients were $107,788.99, leaving a balance of $11,873.38, according to the report of the director, Dr. Harwood L. Hollis, and the board of managers of the institution, presented to the Board of Supervisors on December 7.

A total of 138 patients were treated, of whom 8 were discharged as arrested and 33 sent home as improved. Sixty patients remained in the sanatorium October 31, 1944.

In the period from 1913 to 1944, inclusive, 3,945 were treated at the sanatorium, of which 1,056 were discharged as arrested cases and 1,041 discharged as improved.

Dr. Hollis stated that the eradication program in Oswego county has contributed greatly to the lowering of the death rate and morbidity of this disease.

[Continued from page 330]

He added that while the tuberculosis problem in this area still remained a challenge "to our efforts, satisfactory progress is being made."

"There is much yet to be accomplished and we must continue work on a greater scale if we are to bring the destruction caused by this disease to an irreducible minimum," Dr. Hollis declares.

Reference is made in the report to the action of the Oswego County Health Association in appointing a full-time worker, Miss Virginia Simons, in carrying out the educational program of the antituberculosis campaign. The report of Miss Lucy Vincent, R.N., is also included in the report presented.

The board of managers is made up of Dr. L. D. Pulsifer, president; Dr. H. S. Albertson, F. M. Daley, Frank C. Ash, and Hadwen C. Fuller.*

• • •

Brooklyn's Israel Zion Hospital celebrated a quarter century of service to the borough at a dinner held December 3 at the Waldorf-Astoria Hotel. More than 1,500 persons were expected to attend, and the principal speaker was Representative Emanuel Celler.

Contributions made by dinner guests went toward the current $500,000 campaign to expand the hospital's facilities. According to Hyman Pertnof, chairman of the arrangements committee, a donation of $100,000 was pledged by a New York business man.*

• • •

Receipt of a grant of $4,900 from the John and Mary R. Markle Foundation for a specific problem in research in the radiobiologic laboratory now being constructed at the Long Island College of Medicine was announced on December 9 by Dr. A. Loomis Bell, professor of clinical radiology at the college, and head of the x-ray division of Long Island College Hospital.

As part of the $50,000 development of new laboratories at the college, the fifth floor of the Hoagland Laboratory Building has been converted into the new radiobiologic laboratory.

Dr. Friedrich P. Ellinger, research associate of the department of radiology, has been assigned to the new project designed to increase the efficacy of x-ray treatment in malignant and nonmalignant diseases by the combined use of radiation and drugs. Radiotherapeutic equipment in the department of radiology at the hospital will be used.

• • •

The monthly meeting of the medical staff of Memorial Hospital, Catskill, was held on December 1 at the hospital, when Dr. E. A. Jacobs, roentgenologist at the hospital, presented a paper on x-ray work. Following the meeting a venison dinner was enjoyed.

• • •

The annual meeting of Dansville General Hospital was held on December 6. William J. Maloney, vice-president, called the meeting to order. Members elected Kenneth Plough as chairman and Mrs. Ethel Shepard secretary of the meeting.

James Blum, speaking for Dr. R. J. Maichle, chairman of the house and grounds committee, summarized improvements made during the year including the equipment of a new x-ray room which may be used for emergency operations.*

• • •

Arrangements for the sixth blood donor clinic held on December 8 at Physicians Hospital, Plattsburg, were made by Mrs. Ada H. Rogers, chairman of the Clinton County Chapter of the American Red Cross.*

• • •

A new set of bylaws which provide for several new features in the management of Oswego Hospital were unanimously adopted at a special meeting of the Oswego Hospital Corporation on December 7.

Briefly, the new bylaws provide for a new official to be "director" of the management of the hospital, with the superintendent of nurses and the dietitian being responsible to the director. Creation of a medical staff for the institution is also an important new feature.

It is further provided in the new regulations that any person who contributed $5 or more to the support of the hospital or $25 to the United War Fund or Community Chest and who files a certificate to this effect shall be a member of the Oswego Hospital Corporation and entitled to vote at its meetings.*

• • •

A proposed $31,800 increase of the Grasslands Hospital budget was urged by the Westchester League of Women Voters, the Westchester chapter of the Council of Jewish Women, and the Westchester County Medical Society on grounds there has been a dangerous drop in the hospital's efficiency through payment of low wages.

• • •

Flushing Hospital authorities are awaiting Borough President Burke's reaction to their proposal to widen Parsons Boulevard in front of the hospital.

The proposed widening, designed to eliminate traffic hazards at that point, was submitted to the borough president by Charles U. Powell, Queens topographic engineer, who drew up plans for the project.

It is pointed out that one favorable aspect of the program, which the hospital's board of trustees has fully approved, is the fact that it will not necessitate assessments against private properties in the vicinity as only city and hospital property would be involved in it.*

BENJAMIN WATERHOUSE (1754–1846) AND THE INTRODUCTION OF VACCINATION INTO AMERICA

After the publication in 1798 of Edward Jenner's great monograph on the prevention of smallpox by vaccination with cowpox, the practice of vaccination was taken up very quickly in most civilized countries of the world. Before the turn of the century over 30,000 persons two weeks old and upwards had been successfully inoculated with cowpox. The honor of introducing vaccination into America fell to Dr. Benjamin Waterhouse, the first Professor of Physic at Harvard. Fate as well as the doctor's own mental alertness was instrumental in determining the part he was to play in the control of one of the worst scourges afflicting mankind. He writes: "In the beginning of the year 1799, I received from my friend Dr. Lettsom, of London, a copy of Dr. Edward Jenner's 'Inquiry into the causes and effects of the Variolae Vaccinae or Cow-Pox'; a disease totally unknown in this quarter of the world. On perusing this work I was struck with the unspeakable advantages that might accrue to this country, and indeed to the human race at large, from the discovery of a mild distemper that would ever after secure the constitution from that terrible scourge the small-pox." Desirous of immediately communicating his knowledge of this great discovery to the public as well as to his medical brethren, Waterhouse published a brief account of it in a Boston newspaper, the *Columbian Sentinel*, for March 12, 1799, under the title "Something Curious in the Medical Line."

From Waterhouse we learn that "This publication shared the fate of most others on new discoveries. A few received it as a very important discovery; highly interesting to humanity; some doubted it; others observed that wise and prudent conduct which allows them to condemn or applaud as the event might prove; while a greater number absolutely ridiculed it as one of those medical whims which arise today and tomorrow are no more." Because of the disinclination of the public and the profession to accept the self-evident truth of vaccination, Waterhouse found it necessary to "repeat in America the experiments performed on the other side of the Atlantic." After several unsuccessful attempts to obtain living virus he received in June, 1800, some matter from Dr. John Haygarth, of Bath, with which he successfully vaccinated his own children. After their recovery from this distemper they were publicly inoculated with smallpox but failed to contract the disease. Following these confirmatory experiments he published his first pamphlet on the subject, "A Prospect of Exterminating the Small-Pox," which has now become one of the rarities of medical Americana. A copy of the pamphlet was sent to Thomas Jefferson, then Vice-President and a candidate for the Presidency, who received it enthusiastically and with Dr. Waterhouse's cooperation quickly introduced the practice into Washington and Virginia and subsequently into Philadelphia and other parts of the country. Although there was, because of petty jealousy, much opposition to Waterhouse personally in his attempt to spread the practice of vaccination, Jefferson had sufficient influence and prestige to insure its general acceptance.

That smallpox holds little terror for the world today is due to Edward Jenner's convincing demonstration of the efficacy of cowpox in its prevention. That the blessings of vaccination came so early to the United States of America is due almost entirely to the labors of two men—Benjamin Waterhouse, who introduced it, and Thomas Jefferson, who was largely responsible for its rapid spread and acceptance.—*J. C. Trent, M.D., Thumbnail Sketches of Eminent Physicians, North Carolina M. J., Aug., 1944*

The Diabetic Life Its Control by Dietand Insulin By R D Lawrence, M D Thirteenth edition with wartime supplement Duodecimo of 228 pages, illustrated Philadelphia, Blakiston Co , 1944 Cloth, $4 00

This little volume has already gone into the thirteenth edition, which in itself speaks for the value of the book It is a manual on the treatment of diabetes primarily intended for the patient and contains information which should prove of value to the practicing physician

It is up to date, authoritative, and practical

William S Collens

Deafness and the Deaf in the United States By Harry Best Octavo of 675 pages New York, Macmillan Co , 1943 Cloth, $6 50

The author has prepared this volume from the standpoint of the social economist The subject matter is well arranged and contains a number of tables and statistical surveys This is really an encyclopedia on the subject of deafness and, as such, is a book that should be read not only by otologists but also by economists, public officials, and public health officers The subject of deafness cannot just be set aside and dispensed with as an infirmity or simply as a handicap The author brings these facts out forcefully and discusses them completely in chapters that are well indexed so that the desired information can be readily found The otologist would do well to familiarize himself with the subject matter in this book, for in it he will find information which will be most helpful in assisting him to better understand the hard of hearing and the deaf, and with this newer knowledge, he will be better able to advise and guide those patients who, in the past, have not been adequately handled by the average otologist

ESPECIALLY ADVANTAGEOUS

for the Aged

Adequate strength can be maintained, and the manifestations of senescence can be postponed until ripe old age, if nutritional requirements are properly met. But to accomplish this aim with ordinary foods alone, frequently proves difficult.

As the years advance, certain foods are usually less easily digested. In many instances, organic and functional affections may not only lessen the appetite, but in addition impair the powers of digestion and absorption. In consequence the aged are likely to impose restricted diets upon themselves which perforce cannot meet their nutritional requirements.

Ovaltine, a delicious food drink, made with milk as directed, proves especially advantageous for the aged. It supplies virtually every essential nutrient in readily metabolized form: biologically adequate protein, readily utilized carbohydrate, well-emulsified fat, all the essential vitamins except vitamin C, and the important minerals. How readily three glassfuls of Ovaltine daily can bring the intake of essential food factors to optimal levels, is indicated by the analysis here shown.

Ovaltine is digested with remarkable ease. Its appealing taste is relished by the aged as well as by younger persons.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.

Ovaltine

Three daily servings of Ovaltine, each made of ½ oz. Ovaltine and 8 oz. of whole milk,* provide:

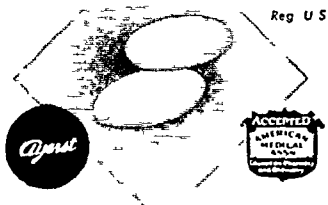
NO. 5 OF A SERIES • • • "PREMARIN" THERAPY AT THE MENOPAUSE

Feeling of Well-Being



It is significant that most of the many published clinical reports on "Premarin" note the fact that patients experienced a general feeling of well-being in addition to relief of symptoms. Rendering the patient symptom-free is, of course, the prime consideration; many physicians, however, feel that the restoration of a brighter mental outlook is also an important consideration when instituting therapy. "Premarin" will be found to exhibit the desirable characteristics of both the natural estrogens and the synthetic substances. Although highly potent, it is derived exclusively from natural sources; it is exceptionally well tolerated, and unpleasant side effects are seldom noted.

Now available in 2 potencies:
No. 866: Bottles of 20, 100 and 1000
No. 867 (Half-Strength): Bottles of 100 and 1000

HIGHLY POTENT

De gustibus non est disputandum

The old Roman adage, "there is no disputing about tastes," is especially true of your patient's preference in contraceptives. • Fortunately, she has equally at her fingertips, a fully dependable contraceptive preparation in cream form, as well as the more familiar jelly. • For Ortho supplies both. Ortho-Creme vaginal cream is pharmaceutically elegant, a worthy companion product to Ortho-Gynol vaginal jelly. Like Ortho-Gynol, Ortho-Creme is readily miscible with vaginal secretions, and effectively spermicidal. It is acceptable to the most fastidious patient, and may be safely employed over a prolonged period without fear of irritation. ORTHO PRODUCTS, INC., LINDEN, N. J.

Active ingredients: ricinoleic acid, boric acid, sodium lauryl sulphate.

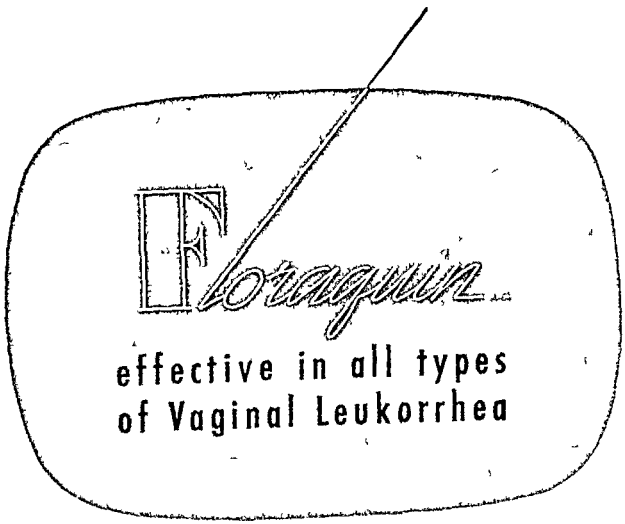
℞ **Pediforme**
FOOTWEAR



for **FLAT-FEET**

The family physician, in health examinations, will not over-look examining the feet of babies and growing children for evidence of flat-feet through heredity tendencies or other causes—and will naturally prescribe measures for correction.

Proper shoes are essential to supplement the doctor's own treatments—but a proper source of supply is essential, too, and the patient of any age-group should be directed to competent and trustworthy fitters of correctly designed shoes of scientific construction. Pediforme footwear have the qualities desired by the doctor and the attractiveness so vital to the sensitive patient.

Convenient sources: **MANHATTAN,** 34 West 36th St. **NEW ROCHELLE,** 545 North Ave

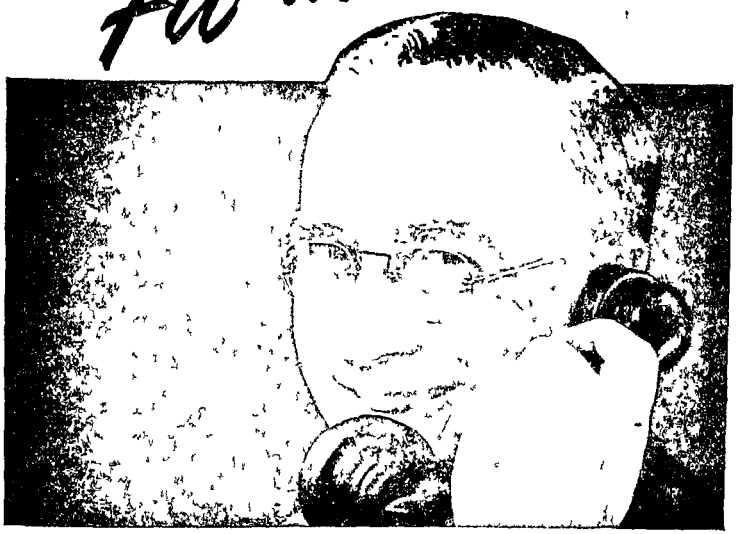
DEPENDABLE ADJUNCT

In ANGINA PECTORIS • ARTERIOSCLEROSIS
• PERIPHERAL VASCULAR DISEASES



Carnacton

Carnacton is a biologically tested extract of highly vascularized and active diaphragmatic muscle with a high metabolic rate . . . providing dependable vasodilator and depressor benefits. Carnacton helps establish collateral circulation and promotes cardiovascular tone and vitality.

Ampuls of 1 cc. and 2 cc.—boxes of 12 and 50; vials of 30 cc. and 50 cc. for oral use. Also 2 oz. vials for injection. For brochure address Dept. N.

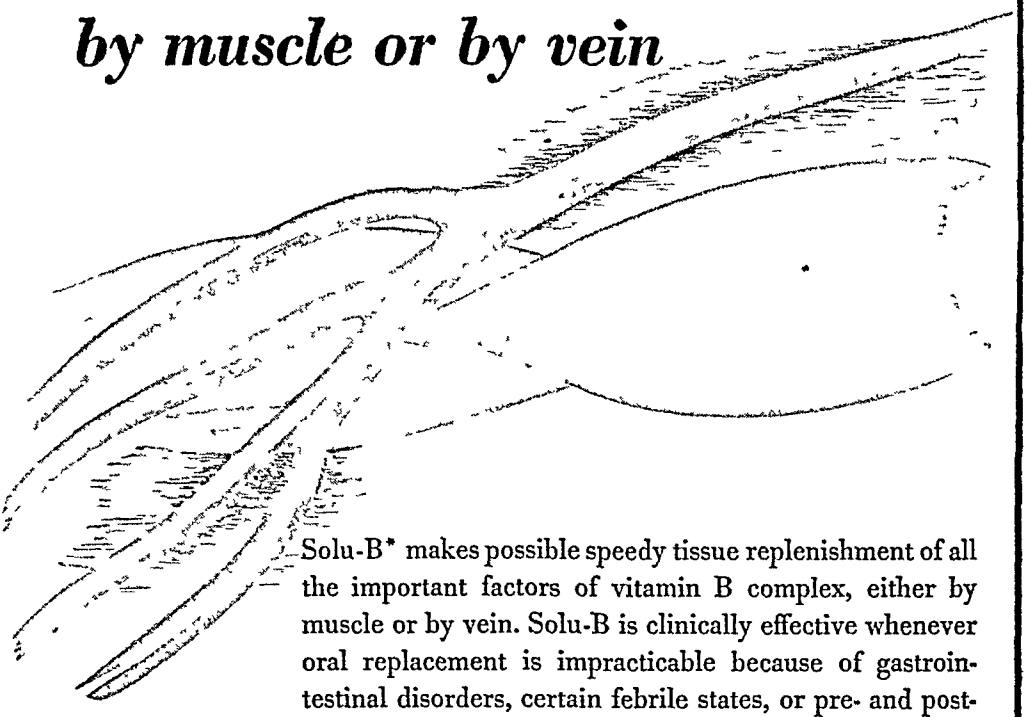
CAVENDISH PHARMACEUTICAL CORP. , 25 West Broadway , New York

Fit at Fifty

Middle age to most men means the peak of their business and social careers To meet these responsibilities, it should also mean the peak of their physical and mental efficiency.

Easy fatigability, exhaustion, insomnia, increasing indecision and irritability, as well as vasomotor, cardio vascular, and genito urinary disorders are often symptoms of endocrine imbalance during the male climacteric

In the male climacteric, Oreton* may be given intramuscularly until symptoms are controlled. Therapy may usually be maintained with Oreton-M* Tablets or Oreton-M Ointment.



*Trade-Marks Reg U S Pat Off

SCHERING CORPORATION

Bloomfield, New Jersey

by muscle or by vein

Solu-B* makes possible speedy tissue replenishment of all the important factors of vitamin B complex, either by muscle or by vein. Solu-B is clinically effective whenever oral replacement is impracticable because of gastrointestinal disorders, certain febrile states, or pre- and post-operative restrictions. Improvement in deficient patients is rapid and dramatic.

SOLU-B is highly stable, instantly soluble, and readily prepared for parenteral therapy. Each 10 cc. vial provides:

Thiamine Hydrochloride	10 mg.
Riboflavin	10 mg.
Pyridoxine Hydrochloride	5 mg.
Calcium Pantothenate	50 mg.
Nicotinamide	250 mg.

Packaged in vials of 10 cc., each vial accompanied by one 5 cc. ampoule of sterile water; in boxes of 5 vials with 5 ampoules of sterile water; and in boxes of 25 vials of Solu-B without water.

MORE EFFECTIVE TOPICAL CHEMOTHERAPY FOR EAR INFECTIONS

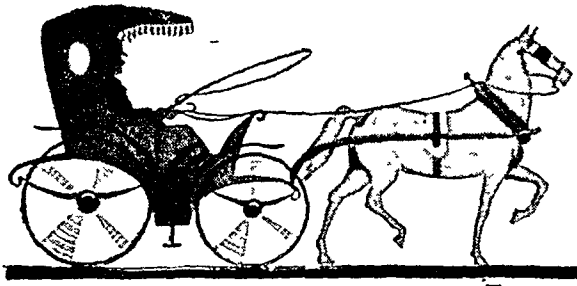
White's

OTOMIDE

Advantages: (1) Antibacterial efficacy, not inhibited by purulent exudate. (2) Gratifying local analgesia. (3) Early remission of discharge and odor in acute and chronic otorrhea.

FORMULA:	W/V
Sulfanilamide	5%
Urea (Carbamide)	10%
Chlorobutanol	3%
Glycerin (high Sp. gr.)	q.s.

Effectively antibacterial, analgesic, hypertonic, yet non-irritating, White's Otomide provides in a stable solution the established clinical advantages of carbamide-sulfonamide.[1, 2, 3] Carbamide (urea) alone has been successfully used in acute and chronic middle ear disease.[4, 5, 6] Its association with sulfonamide enhances antibacterial activity, inhibits sulfonamide antagonists in purulent exudates.



INDICATIONS: Local prevention and treatment of the usual bacterial infections of the middle ear and external auditory canal.

White's Otomide is supplied in dropper bottles of one-half fluid ounce (15cc.)—on prescription only. White Laboratories, Inc., Pharmaceutical Manufacturers, Newark 7, N. J.

for over half a Century

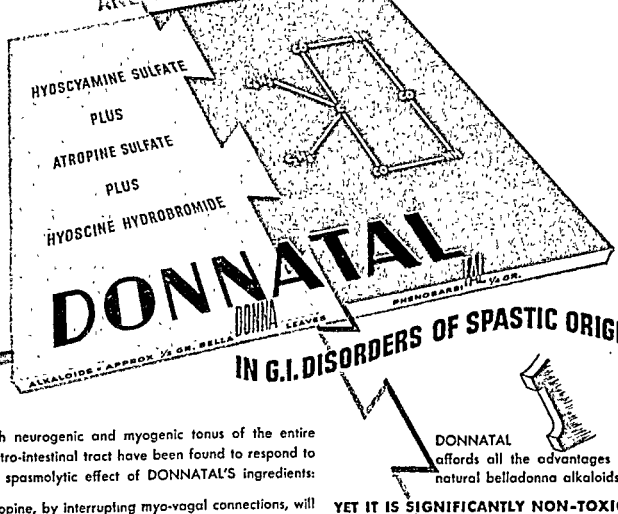
FROM THE TIME of its introduction, in 1893, physicians have consistently and increasingly prescribed LIQUID PEPTONOIDS* WITH CREOSOTE for relief of coughs.

There's a reason for this continued usage . . . and that reason is clinical *results!*

Pure Beechwood Creosote and Guaiacol are combined with predigested beef, wheat, and milk, to form LIQUID PEPTONOIDS WITH CREOSOTE, a palatable bronchial sedative which quiets coughs, promotes expectoration, and helps check the extension of the inflammatory processes. By combining Creosote and Guaiacol with pre-digested proteins, the likelihood of gastric irritation and eructations is reduced.

LIQUID PEPTONOIDS *with* CREOSOTE

Available in bottles containing
6 ounces and 12 ounces.



THE ARLINGTON CHEMICAL COMPANY

*The name PEPTONOIDS is the registered trade mark of The Arlington Chemical Company.

THE SYNERGISTICALLY ENHANCED EFFECT OF

SMOOTH MUSCLE RELAXATION

AND CENTRAL NERVOUS SEDATION

IN G.I. DISORDERS OF SPASTIC ORIGIN

Both neurogenic and myogenic tonus of the entire gastro-intestinal tract have been found to respond to the spasmolytic effect of DONNATAL'S ingredients:

Atropine, by interrupting myo-vagal connections, will relieve spasticity of the upper portion of the alimentary canal, thereby relaxing pylorospasm and tending to re-establish the normal type of gastric secretion. Scopolamine is noted for its sedation of the intestinal structures, and its consequent value in spastic constipation and irritated colon. A relaxing influence similar to that of atropine (though more marked) is exerted by hyoscyamine—upon smooth muscle of the G. I. tract, gallbladder and ureter, providing relief in gastric and hepato-biliary colic, and in sphincter spasm

Phenobarbital helps control the psychogenetic factor —so important in spastic pathologies—by sedation of the central nervous system, supported in certain cases by the central action of scopolamine.

Donnatal is available in bottles of 100 tablets, each tablet containing the formula illustrated above

1 DONNATAL affords all the advantages of natural belladonna alkaloids—

YET IT IS SIGNIFICANTLY NON-TOXIC;

2 DONNATAL provides for the sedation so frequently required—

YET IT IS ENTIRELY NON-NARCOTIC;

AND

3 DONNATAL has marked pharmacologic potency—

YET COSTS LESS

NOT CHOLAGOGUE
NOT CHOLERETIC
BUT HYDROCHOLERETIC

. . . the difference is

CLINICALLY SIGNIFICANT!

Maltbie is proud of having successfully formulated an original process for converting crude viscous ox bile into crystals of chemically pure dehydrocholic acid (Cholan-DH)—the most potent and least toxic agent ever developed for the therapeutic stimulation of free biliary flow. ¶ But far more important than the process itself, is the remarkably salutary effect of Cholan DH in providing maximally efficient drainage of the biliary tract—in contrast to older measures which only cleared the gallbladder of its concentrated contents, or stepped up biliary flow without reducing its viscosity or relieving gallbladder stasis. ¶ Physicians are now employing Cholan DH in the effective non surgical management of many biliary tract disorders ¶ Available for oral use in tablets of 3¼ gr. each.

CHOLAN·DH

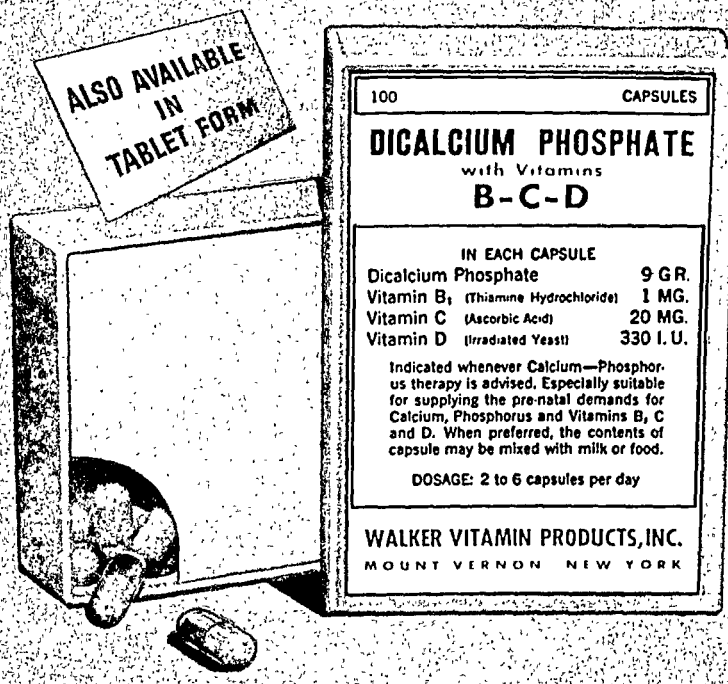
THE E. L. PATCH COMPANY BOSTON MASS.



FOR PRENATAL CARE

DURING pregnancy, not only must an adequate intake of calcium and phosphorus be assured, but also a liberal supply of vitamin D for peak calcium metabolism . . . vitamin B_1 for sound nerves and the amelioration of hyperemesis gravidarum . . . and vitamin C, to supply the greatly increased requirements of pregnancy and lactation.

Walker's Dicalcium Phosphate with Vitamins B-C-D provides all these factors in one "single-prescription" product.

Its capsule form eliminates the "chalky" taste of wafer products,—its tolerance is excellent (the Vitamin D is supplied in the form of irradiated yeast);—and the price to the patient is only $1.75 per box of 100 capsules.

***For a trial supply, just write to* WALKER VITAMIN PRODUCTS, INC • MT. VERNON, N.Y.**

Walker's

Faster Response

IN SECONDARY ANEMIA

In the correction of the anemic state Livitamin not only leads to rapid hemoglobin regeneration, but also aids in the eradication of the usually associated conditions. Its iron is highly available and promptly utilized; its contained liver concentrate presents the fractions found valuable in the anemias; its rich store of B-vitamins overcomes the frequently severe anorexia and corrects the nutritional deficiencies which almost invariably are encountered in hypochromic anemia. Since Livitamin is in liquid form, dosage is easily regulated. Its palatable taste is appreciated by all patients, and especially by children.

LIVITAMIN

Each fluidounce of Livitamin presents.

Fresh Liver (as liver concentrate)	2 oz.
Thiamine hydrochloride (B_1) (3 mg.)	1000 U.S.P. Units
Riboflavin (B_2, G)	1 mg.
Nicotinamide (niacinamide)	25 mg.
Pyridoxine hydrochloride (B_6)	1 mg.
Pantothenic acid	5 mg.
Filtrate factor	20 J. L. Units
Iron and Manganese peptonized	30 gr.

In doses of 2 to 4 teaspoonfuls t. i. d. Livitamin rapidly corrects hemoglobin deficiency. Available in 8-oz. bottles.

"Doin' all right, thank you, Doc!"

Of course, he's doing all right! Didn't his doctor suggest the hearty, appetizing bowl of Heckers' Cream Farina he downs every day? His doctor knows that Cream Farina's been a staunch stand-by for a baby's first solid food for almost a century.

And Cream Farina's better than ever now. It's enriched. It has valuable Vitamin B1 added to it; it has niacin added; it has nutritional iron added. No wonder babies thrive on it! And no wonder mother feeds it to the whole family! There's no trouble getting them all to eat a hot cereal either, if you give them Cream Farina —they love that creamy heart-of-the-wheat goodness.

Quick to cook, quick to nourish, quick to digest, Cream Farina is tremendously satisfactory as a first solid food for baby. And busy mothers will be grateful for a good baby cereal that's a time-saver, because they can serve it to everybody. So you're doing mothers a double favor when you recommend delicious Cream Farina.

The Grand Baby Cereal That The Whole Family Loves

Would You Like a Package of Heckers' Cream Farina?

FULL-FLEDGED COOPERATION

MAXIMUM patient cooperation in intestinal bulk therapy is assured by Mucilose, a highly purified hemicellulose which provides *greater bulk* from *smaller doses* at *lower cost*. Published data* show that Mucilose yields much more bulk than other well-known psyllium-base products. Doses are correspondingly smaller, and savings in cost to the patient average 65%.

composed of the highly purified ... of Plantago loeflingii.

LUBRICATING BULK is provided by the absorption of approximately 50 parts of water to produce a colloidal gel.

BLAND, hypoallergenic, and free from irritants, it is also non-digestible, non-absorbable, and chemically inert in the digestive tract.

dietary measures for the control of constipation in aged, convalescent and pregnant patients.

DOSAGE: 1 or 2 teaspoonfuls in a glass of water, milk, or fruit juice once or twice daily, followed immediately by another glass of liquid. It may also be placed on the tongue and washed down, or it may be eaten with other foods. Ample fluid intake is advisable to assure maximum bulk formation.

VASODILATATION in Arterial Hypertension

	ACTION BEGINS	MAXIMUM EFFECT	DURATION OF ACTION
AMYL NITRITE	1 MINUTE	3 MINUTES	7 MINUTES
NITROGLYCERIN	2 MINUTES	8 MINUTES	30 MINUTES
SODIUM NITRITE	10 MINUTES	25 MINUTES	60 MINUTES
ERYTHROL TETRANITRATE	15 MINUTES	32 MINUTES	**3 to 4 hours**

Comparative effects of commonly used nitrites on systolic blood pressure in normal individuals. The action of Erythrol Tetranitrate Merck begins in 15 minutes and persists for three to four hours.

Among the various preparations available for the treatment of arterial hypertension, Erythrol Tetranitrate offers the advantage of producing a reduction in blood pressure sufficiently prolonged so that administration three times daily may maintain the reduction. This effect of prolonged vasodilatation, beginning within a short time after oral administration, is not obtained with any of the commonly used nitrites.

Erythrol Tetranitrate may be prescribed over a prolonged period with sustained effect. By dilating the peripheral arterioles, it tends to decrease not only the stress of excessive pressure on the arterial walls, but also to relieve the burden on the heart.

DILEMMA

He has a headache

He also has "sour stomach."

Should he take aspirin?

Yes, provided . . .

This long-standing dilemma does have a solution. Physicians employing PRO-DOL for relief of pain know that:

PRO-DOL affords effective aspirin therapy buffered and insulated against side-effects of plain aspirin, without the disadvantages of alkalis.

PRO-DOL incorporates 5 grains of aspirin with 7½ grains of dried aluminum hydroxide gel in each full dose. As aspirin's irritating acids of hydrolysis form in the stomach, they are *immediately* neutralized and adsorbed.

This ethically promoted analgesic entails neither interference with peptic digestion nor compensatory rise in gastric acidity. An exclusive feature insulates aspirin from gel within each tablet until used.

DOSAGE: 1 or 2 tablets, repeated as required, for relief of headaches, neuralgias and muscular aches and pains.

HOW SUPPLIED: Boxes of 24 and 60 flavored tablets, each tablet individually wrapped in Sanitape.

Professional samples and literature on request.

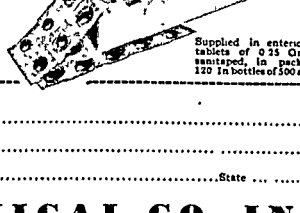
Meeting the patient's expectations

...and yours...

in the treatment of Urinary Infections

The patient suffering from pyelonephritis, cystitis, prostatitis and other distressing urinary infections desires and expects to receive prompt and effective therapy.



Similarly, the physician—beset with the difficulties engendered by a greatly increased practice—can ill afford the lengthy, troublesome and frequently ineffective treatment which results from the employment of certain urinary antiseptics.

Mandelamine, the chemical combination of methenamine and mandelic acid, has proved itself to be a really efficient and trouble-free antiseptic, adequately meeting the expectations of patient and physician.

Literature and a physician's sample will be sent to you upon request.

THE EMPIRE STATE'S CONTRIBUTION TO THE MEDICAL PROFESSION

It's All in the Bottle

In preparing liver concentrates for use as hematinics, all too often refining defeats its own purpose. Too much refining removes valuable hemoglobin-building fractions which are then discarded—down the drain.

HEPATINIC
'MCNEIL'

—when employed in the management of secondary anemias—gives assurance that the *full* therapeutic value of liver concentrate is present. The liver concentrate incorporated in palatable Elixir Hepatinic is in a crude, unfractionated form, thereby supplying certain hemoglobin-building substrates not available where liver is concentrated by excessive refining.

You will be pleased with this significant feature of Elixir Hepatinic.

Each fluidounce contains: Ferrous Sulfate 12 gr., Crude Liver Concentrate (equivalent to 660 gr. fresh liver) 60 gr., Thiamine Hydrochloride 2 mg., Riboflavin 4 mg., Niacinamide 20 mg, together with pyridoxine, Pantothenic acid, Choline and other factors of the vitamin B complex.

Elixir Hepatinic is supplied in bottles of one pint and one gallon

Not Merely the Joints

REQUIRE TREATMENT IN ARTHRITIS

Systemic Involvements, too— DEMAND CONSIDERATION

Weakness • Fatigability • Loss of Weight • Anemia
Neuritis • Gastrointestinal Disturbances • Liver Dysfunction
Impaired Carbohydrate Metabolism • Early Arteriosclerosis

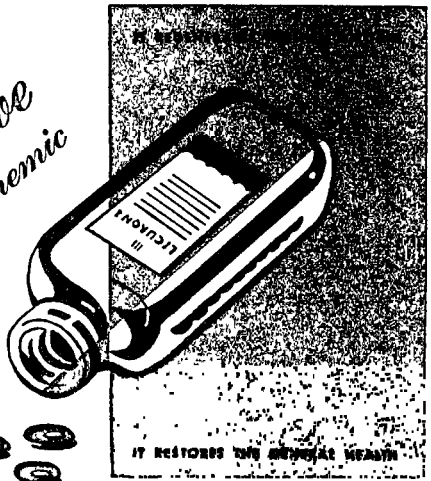
THE measurable improvement, systemic as well as articular, which usually follows the use of Darthron is due to its pharmacodynamic influence which is exerted not only on the joints but also on the general systemic state.

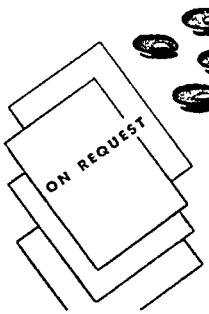
Maximal improvement in the shortest time may be achieved only when efficiency of all metabolic and physiologic activity is raised to and maintained at optimal levels.

The pharmacologic influence of each of its nine active ingredients, upon which the rationale of the Darthron formula is based, is time-tested and clinically proved. The need for each is well established.

Darthron supplies in a single capsule all nine of these essentials. By eliminating the need for taking a number of different medicaments, Darthron makes for convenience in administration and better patient cooperation. Physicians are invited to send for a complimentary copy of the new brochure "Systemic Therapy in the Arthritides."

J. B. ROERIG & COMPANY
536 Lake Shore Drive • Chicago 11, Illinois





Each Capsule Contains:

Vitamin D	50,000 U.S.P. Units
Vitamin A	5,000 U.S.P. Units
Ascorbic Acid	50 mg.
Thiamine Hydrochloride	2 mg.
Riboflavin	1 mg.
Pyridoxine Hydrochloride	0.1 mg.
Calcium Pantothenate	0.333 mg.
Niacinamide	10 mg.

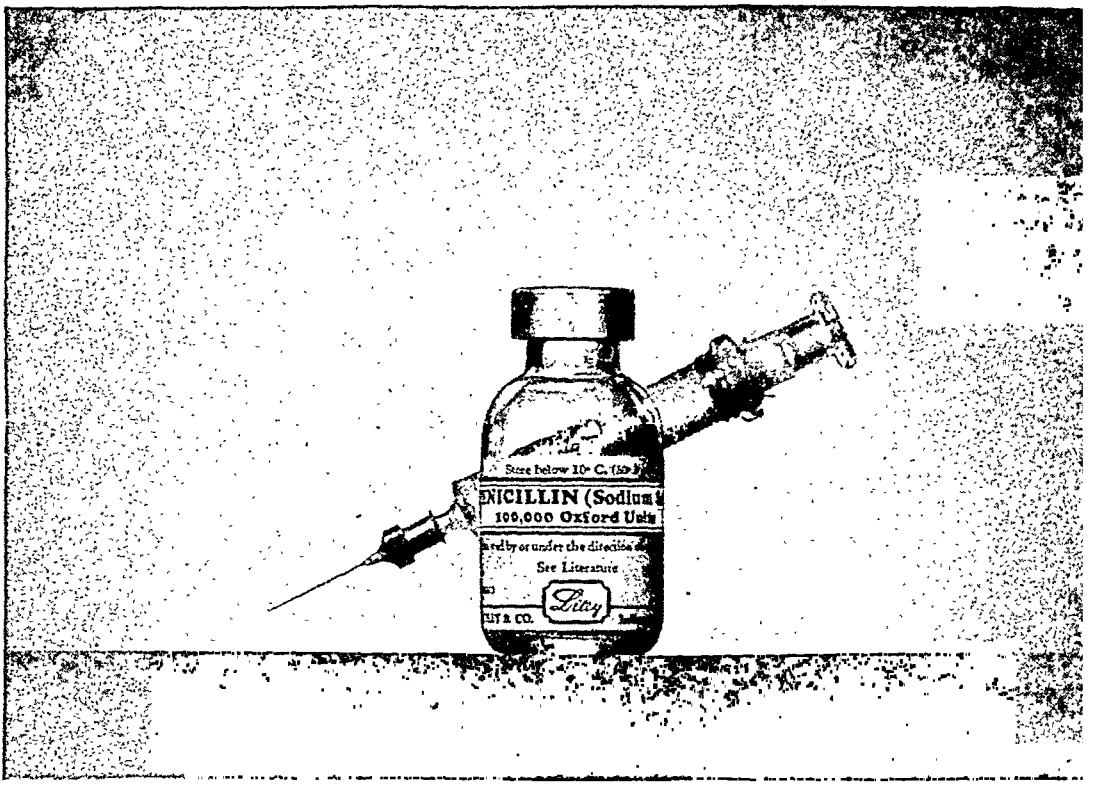
Bi-active
Antianemic

Actual
CASE HISTORIES



. . . . . of hypochromic anemia in which the rapid hemoglobin regeneration effected by Licuron-B is graphed against periods of no medication and periods in which iron alone was administered.

All too frequently subclinical deficiencies in the vitamin B complex withhold the feeling of well being which the patient should have experienced following correction of hypochromic anemia.

However, when Licuron-B is administered, the natural and synthetic B-vitamins which it provides raise the nutritional status of the patient. Simultaneously the correct copper-iron ratio in this bi-active antianemic restores the optimal level of hemoglobin.

LAKESIDE LABORATORIES, *Milwaukee, Wisconsin.*

Licuron-B

Penicillin...today's wonder drug

MORE PRECIOUS than the gold it resembles is the pinch of yellow dust in the bottom of a 20-cc., sterile, rubber-capped ampoule of Penicillin. This far-famed metabolic product of the lowly mold *Penicillium notatum* is a veteran performer of many miraculous cures. While the pharmaceutical industry was exhausting every resource to increase production of penicillin over and above the urgent needs of the armed forces, the drug was released for civilian use only in desperate cases, in many of which other treatment had failed. In this rigorous proving ground, penicillin has skyrocketed to fame.

The unique problems involved in the mass production of penicillin are rapidly being solved. The product has been purified to the point where it seldom causes side-effects or reactions. Safe, dependable, and pure, Penicillin, Lilly, represents a notable achievement in pharmaceutical excellence. Eli Lilly and Company, Indianapolis 6, Indiana, U.S.A.

Editorial

Nurses for the Armed Forces, III

This JOURNAL is doing what it can on behalf of the physicians of the State to assist in the procurement of needed nurses for the armed forces. No request has been made from any governmental source for such assistance from us or from any of the state medical journals, as far as we are aware. Yet these medical journals are read by the physicians who, with the civilian hospitals and the patients, are being blamed for the failure of the nurse procurement program.

Perhaps it is considered by higher authority that this problem is simply none of our business. The fact remains, however, that we write for the information of 18,000 physicians of this State twice a month, and we consider the welfare of the wounded of the armed forces of sufficient moment to attempt to get them, asked or not, the nursing help they need while at the same time recognizing the necessity for the maintenance of a proper balance of nursing care in our civilian hospitals and industries.

Assistance from the physicians of the State in the nurse procurement program can be had and will be unfailingly given only if the doctors are continuously, and, preferably, truthfully informed as far as this can be done. They want to know:

1. Whether the Army and Navy nurse personnel is being as conservatively utilized as possible?

2. How much assistance is being provided for nurses already in service by (*a*) medical corpsmen and (*b*) ward attendants, either civilian employees or draftees inducted on a limited service basis?

3. To what extent male nurses are being utilized? Why they are not commissioned, if necessary? Are they being utilized in forward areas with high casualty expectancy, and if not why not?

4. What use is contemplated for the physically acceptable number of the 9,000 negro nurses who are said to be willing and even eager to serve their country? Is there no place for them?

5. Why are U.S. Cadet Nurse Corps prospects informed on page 4 of the *Fact Sheet* that "In return for advantages received through the Corps, *Cadet Nurses promise* that, health permitting, they will remain in essential nursing for the duration of the war. The choice of which essential

service is theirs. *They are not required to pledge themselves* to military service."?

6. What use, if any, is to be made, if only for the present emergency, of 4 F's, as auxiliary nursing aides or ward attendants? The. J.A.M.A.[1] shows upwards of 200,000 of these as rejected for "*eyes*" alone, and over 100,000 for "*ears*" alone, and over 50,000 for "*under-*" or "*overweight.*" How about some of the slightly under 250,000 who were rejected for *hernias?*

Doctors (and nurses) read the newspapers, also. They may have read[2] an article by Hanson W. Baldwin, from which we quote:

"The suggested draft of nurses for the fighting services should be considered in relation to personnel problems within as well as outside the services.

"Some Army doctors feel that some hospitals in this country, especially Air Forces hospitals, may actually be overstaffed with nurses and that if the Army distributed available nurses somewhat better, there would be more nurses overseas and in hospitals where they are most needed.

"But one of the main problems of the Army Nurse Corps is a problem of morale. The nurses are well aware of the glamour and the publicity and the increased rank and prerogatives given to or acquired by the Wacs. They resent what seems to them subordination of the Nurse Corps to the Wacs. The ranks of captains, majors, or even of first lieutenants are few and far between among the nurses overseas, yet the nurses are usually much farther forward, run greater risks, and have far harder work, requiring far longer professional study than do most of the Wacs who may be captains, majors, or even lieutenant colonels. These inequities are a part of the Army's nurse problem."

How shall we answer that one?

Or they may have read[3] Dorothy D. Bromley, who reports a joint interview of twenty registered nurses. They held, and we incline to agree:

"that a draft of nurses would be unfair discrimination if it were not coupled with a national selective service act applicable to all women."

Also:

"It was felt that more nurses should be taken for limited service in this country. A nurse of 39 who admits she is not doing essential work as a doctor's office nurse asked for such service because she is the only child of a father who is 78 and an ill mother. She was refused, as limited service is only granted for medical reasons.

"All of the group thought the 1,200 graduate members of the Cadet Nurse Corps, who have received part of their training at government expense, and the 25,000 who will graduate next spring, should be obliged to enter military service before there is a draft.

"While there was a boom in nurse recruiting last week following the President's speech calling for a draft of nurses, members of this group resented as 'unfair' the proposal to draft them into the Army as privates. They argued that more nurses would enter the services if they were assured they would not have to take care of soldiers' wives in military hospitals—a kind of duty that has disgruntled more than a few Army nurses they know. . . ..

"There was general criticism of Red Cross and military red tape. . . ..

"The group argued, and with logic, that the Army and Navy would have more nurses today if they relaxed their rigid rules. They told of a nurse turned down by the Navy because she 'had an uneven bite,' and another because 'she had two teeth missing.' Several were said to have been rejected by the Army because they were 'seven-eighths of an inch too short,' or were as little as five pounds underweight. . . ..

"An older woman made the point that the fear of joblessness after the war haunts nurses, who are not covered by social security. That is the reason nurses with good jobs are inclined to hold on to them. . . . ."

We submit that there is much that needs clarification, perhaps more that needs revision of policy and practice if the needed nurses are to be obtained for the armed forces. Doctors will be glad to help in any way they can. It would seem that much could be done short of drafting nurses, and we hope it will be done. Drafting should be the last resort.

We demand a *National Service Act* in accordance with accepted principles of constitutional government. We still have a Republic. We propose to keep it.

Adequate Diet III: Mineral Elements

Largely on the basis of animal experiments, it appears that fourteen different mineral elements are to be regarded as essential dietary constituents. The body contains twice that many. It is rather amazing that such elements as lead, bromine, and aluminum have been detected in the tissues even of the newborn. Most of the body minerals which are not now classed as essential are undoubtedly present merely because they occur in the food eaten and are not completely excreted. It is probable that some of them may play a useful role which is as yet unknown.

Fortunately, in selecting diets we need give attention to only a few of the fourteen essential minerals because most of them are always supplied adequately in whatever combination of foods is chosen. Calcium, phosphorus, iron, and iodine are the ones needing special consideration.

Calcium and phosphorus are the two minerals which are required in largest amounts. They play their major role, along with vitamin D, in bone development during growth and in pregnancy, and for lactation. They are also needed throughout life to maintain the bony structures, and for many other physiologic processes. Special attention is required in food selection in order that the dietary need for calcium may be met. A liberal intake of milk is by far the most effective way of meeting this need. Milk is an excellent source of phosphorus as well. Diets which are adequate in protein and calcium can generally be relied upon to furnish enough phosphorus also.

Common salt, in the amounts habitually consumed, supplies far more than is needed of the essential elements, sodium and chlorine. The usual diet also contains adequate amounts of potassium. This appears to be true for magnesium as well. The recent report of Miller,[1] however, describing a case of tetany in which blood magnesium was low and in which magnesium feeding resulted in a rise in the blood level and a relief from the symptoms, suggests that under certain conditions this element may be deficient. Magnesium tetany occurs in practice with certain farm animals.

The adult requirement for iodine is about 0.15 to 0.30 mg. daily. During adolescence and pregnancy, the requirement is slightly higher and of special importance. People living near the seacoast, and in certain other areas where the soil is rich in iodine, obtain this requirement from their food and water supply. In other areas, where the soil is depleted of iodine, goiter is often endemic and the need for supplemental iodine in the diet is well understood. There have been exponents of the idea of adding iodine to the drinking water. By this method the adolescent received sufficient iodine to prevent colloid goiter, but as the physiology of the thyroid gland became better known, it was found that some thyroid disturbances in adults were accentuated by the increase in iodine intake. For this reason, adding iodine to drinking water has been largely discontinued in favor of supplementing the individual's iodine need. Thus the use of iodized salt, which contains about 0.01 per cent of potassium iodide, has become more extensive.

While it is not difficult to select a diet adequate in iron, it is clear that many diets are deficient in this element at times when the need is greatest—namely, during growth and pregnancy. Although the red corpuscles are being formed and destroyed throughout life, the iron of the broken-down hemoglobin is almost entirely reutilized. Thus, aside from losses in menstruation and hemorrhage, the need for dietary iron is small in the case of the adult. About one-tenth as much copper as iron is required to assist hemoglobin formation. No special attention seems needed to assure an adequate supply of copper in the diet.

Sulfur is an essential constituent of body proteins, but to serve this purpose it must be supplied in the diet in the sulfur-containing amino acids or in related organic combinations. Thus, inorganic sulfur as such is valueless and needs no consideration.

Fluorine has long been thought of as a harmful rather than a useful element because it is found in the water supplies of certain areas in sufficient amounts to cause mottled enamel, and even to injure tooth

and bone structure. But this element is a constant, and presumably normal, constituent of the teeth and bones, and evidence is accumulating that a certain minimum level of intake may be actually beneficial in retarding the incidence of dental caries. This evidence has come from epidemiologic studies. Arnold and associates[2] found, for example, that there was three times as much caries in Quincy, Illinois, where the water supply contained 0.2 p.p.m. of fluorine as in Galesburg, Illinois, where the level was 1.8 p.p.m. Other reports, such as the one by Knutson and Armstrong,[3] indicate that the topical application of fluorine lowers the incidence of caries. They suggest a desirable level of 1 p.p.m. of fluorine in the water supply, and state that there is no evidence that this level is harmful or causes discoloration. Smith and Smith[4] have reported, however, that levels of fluorine which seem to lessen caries early in life cause a much more rapid breakdown of the teeth later. Until longer-time observations are made, it would seem wise to follow a conservative course in connection with proposals for stepping up the level of fluorine intake in any area.

Manganese, zinc, and cobalt, along with copper, which has previously been discussed, are generally classed as "trace elements" because they are needed by the body in such minute amounts. These elements have received little or no attention in the case of man, because it has been assumed that the diet always contains enough to meet any needs. It has recently been found that a lack of manganese is responsible for serious abnormalities of bone growth in chickens. A deficiency of cobalt has been responsible for the deaths of hundreds of thousands of grazing animals in various parts of the world.

As little as one-tenth of a milligram of cobalt, an amount which could be held on the end of a pin, makes the difference between life and death in a sheep. These facts indicate the outstanding significance in animal nutrition of some of these elements which have been little studied. It seems that we should give more attention to the trace elements in human nutrition. Certainly there are no widespread acute deficiencies such as have been noted in farm animals grazing on certain soils, but there may be subacute troubles which have escaped notice and which continue to impair health efficiency, as has recently been found true for some of the vitamins.

The Annual Meeting Canceled

On January 11, as a contribution to the more vigorous prosecution of the war, the Council of the Medical Society of the State of New York, in response to the government's request for cooperation in lightening the load on the Nation's transportation system, canceled its annual meeting, scheduled to be held at Buffalo, New York, April 30–May 3. The meeting of the House of Delegates will be held, unless further government restrictions on travel are announced.

"The Society feels it should restrict this meeting to the minimum necessary to conduct the affairs of the organization. It will cut down attendance from approximately 3,000 expected at Buffalo to 200 officers and delegates who will transact the important phases of the Society's participation in the war effort. All scientific sessions have been canceled as well as social features which usually accompany these meetings."

The JOURNAL calls to the attention of all Section Chairmen the fact that this cancellation will possibly operate to reduce the volume of scientific papers which are ordinarily available after the Annual Meeting for publication in these pages. Doubtless a considerable number of these papers have already been prepared or are now in preparation. Such scientific papers as would have been presented at the various section meetings will be welcomed as usual by the Editors. We must, however, inform all Section Chairmen and our various authors that further curtailments of printing paper

stock are anticipated in 1945. With this in view, we suggest that before they submit their scientific papers to their respective section chairmen, all authors observe the following suggestions:

1. Make a *brief* abstract of the topic of the paper; one or two short paragraphs will usually do. Leave a *triple* space before commencing the first paragraph of the scientific paper proper.

2. If reporting cases, brief them as much as possible; do not cite two cases if one will suffice.

3. Eliminate all charts, graphs, and pictures if possible. If these are *essential* make them few.

4. *IMPORTANT:* Since the papers will *not* be read this year, they should be written, or if already written, be revised for publication. The JOURNAL is published principally for *general practitioners*. They want practical, concise aids to diagnosis and treatment. They have limited time to read. The editors ask the help this year of all contributors to make the content of the articles as concise and practical as possible.

Section chairmen can assist the Editors to meet the extraordinary conditions imposed upon this JOURNAL by the cancelation of the Annual Meeting, by bringing the foregoing suggestions to the attention of their authors.

"To compensate for the loss of the educational advantages of scientific sessions, we are augmenting the postgraduate courses held locally throughout the state under the supervision of Dr. O. W. H. Mitchell, of Syracuse, Chairman of our Committee on Public Health and Education. These provide for institutes held at various sections of the state throughout the year at which attendance is local and only a few speakers are on programs coming from distant points." It is fortunate indeed that the Society has stressed and expanded its postgraduate teaching program to the extent illustrated by the 1944–1945 *Course Book*. The regional programs can thus substitute for as they have previously complemented the scientific sessions of the Annual Meeting.

More fight, less talk.

Stay home. Buy War Bonds.

Walter P. Anderton, M.D.

Dr. Walter P. Anderton, a practicing physician in this city since 1913 and assistant professor of clinical medicine at Columbia University's College of Physicians and Surgeons, was appointed secretary of the Medical Society of the State of New York at a meeting of the Society's Council January 11. He succeeds the late Dr. Peter Irving.

Dr. Anderton is associate attending physician at Presbyterian Hospital, where he has served on the medical staff since 1915.

He is also consulting physician at the French and Knickerbocker Hospitals, New York City, and the Newport, Rhode Island, Hospital. He is assistant professor of clinical medicine, Columbia University, College of Physicians and Surgeons.

The new officer is a member of the American Medical Association, the Medical Society of the State of New York, and the Medical Society of the County of New York, of which he is a past-president. He also served on the county society's committee on legislation and was secretary of the board of censors. He has served as a member of the House of Delegates of the American Medical Association and the House of Delegates of the Medical Society of the State of New York.

Active in many other professional societies, Dr. Anderton holds membership in the New York Gastroenterological Association, the National Tuberculosis Association, the American Heart Association, the Harvey Society, the Quiz Medical Association, of which he is a former president, and the Association of the Alumni of Bellevue Hospital. He is also a Fellow of the American College of Physicians and the New York Academy of Medicine, president of the Francis Asbury Fund, and a trustee of the New York Dispensary.

Dr. Anderton received his A.B. degree at Harvard College in 1908 and his M.D. at the College of Physicians and Surgeons of Columbia University in 1911. He interned at Bellevue Hospital and received his New York State Medical License in 1913.

J. Richard Kevin, M.D.

Dr. J. Richard Kevin, past-president of the Medical Society of the State of New York, died January 8, 1945, at his home in Brooklyn.

Born in LaCrosse, Wisconsin, in 1863, he attended the University of Vermont and graduated from Bellevue Hospital Medical College in 1888. He interned at St. Mary's Hospital, Brooklyn, and remained on the staff thereafter as attending surgeon and then as senior surgeon until the time of his death.

Dr. Kevin was elected to membership in the Medical Society of the County of Kings in 1889 and became its president in 1914. He was one of the original Fellows of the American College of Surgeons in Brooklyn and became President of the Brooklyn Surgical Society in 1909. He was a member of the Brooklyn Pathological Society and member of the Associated Physicians of Long Island, also a member of the Alumni of St. Mary's Hospital, Brooklyn, and President of the Hospital Surgeons Association in 1914. He was Surgeon of the 23rd Regiment, New York National Guard, and went with that regiment to the Mexican Border as a major in the Medical Corps in 1916.

Postgraduate Medical Education, 1945

The activities of the Medical Society of the State of New York with respect to its program of instruction offered each year are again extended and broadened.

The Council Committee on Public Health and Education arranges for instruction in a wide variety of subjects. This program is made available through the combined efforts of the members of the Medical Society of the State of New York, the faculties of medical schools and research institutions, the New York State Department of Health, the Dental Society of the State of New York, the Division of Industrial Hygiene of the New York State Department of Labor, and several other organizations and associations.

A considerable part of these activities is presented in cooperation with the New York State Department of Health. In addition to the courses arranged as series of lectures, speakers on many subjects are available for a single lecture before county medical societies, hospital staffs, and other medical groups. The Committee also arranges instruction for a one-day session designated as a "Teaching Day." A teaching day is a combination of clinics, demonstrations, and lectures for an afternoon and evening. The State Dental Society and the Medical Society of the State of New York have a Joint Committee on Dental Health. This Committee, in cooperation with the New York State Department of Health, has arranged an interesting and informative program which is now available, also. For most of the instruction the lecturers will, upon request, substitute a clinic for the lecture if appropriate patients and facilities are available. This information must be given at the time the request for instruction is made.

Occasionally a county society, hospital staff, or some other medical group desires a program which is not specifically mentioned in these announcements. Should the program, whether clinic, demonstration, lecture, or combination, be one which the Committee can arrange, they will be glad to do so.

The new course book for 1944–1945, which has just issued from the press, features industrial health, treatment of common diseases, diagnosis and treatment of meningitis, and tropical medicine. These subjects have been included in former years, it is true, but the content of the courses has been enlarged. The courses on ophthalmology, penicillin therapy, psychiatry, home and farm accidents are new.

It is to be hoped that county societies, hospital staffs, or other medical groups will take full advantage of the facilities offered in the *Course Outline Book*. All inquiries should be addressed to the Chairman, Council Committee on Public Health and Education, 428 Greenwood Place, Syracuse 10, New York. Copies of the new *Course Outline Book* are on file with the secretary of every county medical society.

ADVANCED CANCER OF THE PROSTATE*

A Consideration of the Value of Radical Prostatectomy in Selected Cases

A LAURENCE PARLOW, M D , Rochester

(From the Department of Surgery Division of Urology of the University of Rochester, School of Medicine and Dentistry, Rochester, New York)

APPROXIMATELY four years ago Huggins and his coworkers[1] described the results of their studies of the effects of the administration of androgens and estrogens on the production of prostatic secretion in dogs These investigators showed that androgens activate prostatic epithelium with a resultant increase in the production of prostatic fluid Estrogens were found to stop the production of prostatic secretion and also to cause a regression of the epithelial cells They also noted that androgens administered to patients with cancer of the prostate produced an increase in the size of the cancer and an exacerbation of their symptoms As a result of these observations, Huggins began to castrate men who had advanced cancer of the prostate and reported the almost miraculous clinical improvement that ensued Not only did the primary cancer regress but there also occurred a disappearance of metastatic nodes At long last we had something encouraging to offer the unfortunate individual who had heretofore hopeless condition

Soon reports were published by staff members of various clinics describing the results of prostatic cancer treated by orchiectomy Nesbit and Cummings[2] observed a favorable response in 73 per cent of 75 cases followed over a period of six months Fifteen cases were considered to be failures and 10 cases were noted as delayed failures Alyea and Henderson,[3] in a series of 40 cases followed over a period of one year, reported an immediate general improvement in all cases Relief of metastatic pain was most remarkable Only one of their patients died of carcinomatosis and one other patient had a delayed failure after eight months Dean, Woodward and Twombly,[4] in an excellent paper, concluded that the majority of patients treated with surgical castration and estrogens, after a variable period of improvement, relapse and die of the disease Herger and Suer,[5] as a result of a study of a series of 82 cases followed over a period of twelve months, arrived at a similar conclusion Kretschmer[6] described his results as anything but desirable Kahle, Schenken, and Burns,[7] in a very thorough study, reported favorable results with the administration of rather large amounts of diethylstilbestrol over a period of three years These investigators pointed out that their studies provided no evidence that cancer of the prostate could be cured by the use of estrogens On the other hand, they did demonstrate that primary and metastatic lesions would regress and that life could be prolonged in comfort

Thus, a review of the literature reveals that the greater number of cases of cancer of the prostate with metastasis treated with castration and estrogens show immediate clinical improvement Regression of both the primary and metastatic lesions, with resultant disappearance of pain and urinary distress, is the usual result These cases also show an apparent return to normal health In many patients, however, the improvement is only temporary Finally, there is a group of cases in which the disease continues its course uninterruptedly despite the treatment with castration and estrogens One also notes the development of two schools of opinion regarding the management of these cases One group advocates the use of stilbestrol therapy and the other group recommends surgical castration plus the use of estrogens However, one observes also that while both factions believe that they are able to obtain corresponding alleviation of symptoms and regression of the disease as a result of therapy, they are fully agreed that neither form of treatment will produce a cure Regarding these therapeutic measures, it is of interest to heed the experience of Alyea and Henderson,[3] who report that the regression of the carcinoma was more complete in patients treated with orchiectomy than in those patients treated with diethylstilbestrol

In view of such information, debate, agreement, etc , it is only natural for one to review the results of therapy in cases of advanced carcinoma of the prostate immediately available to him, keeping in mind the question Is there anything more one can do to effect a cure of the disease? The term "advanced carcinoma of the prostate" is used to indicate the type of case in which the disease is no longer confined within the capsule of the prostate, metastasis has occurred and a radical operation is considered as offering no permanent benefit

---

Read at the Annual Meeting of the Medical Society of the State of New York New York City May 10 1944

* This investigation was supported with funds from the Dr Henry C Buswell Memorial

During the period between January, 1941, and November, 1943, 75 cases of advanced cancer of the prostate were treated with orchiectomy. Eighteen of these cases received prostatic resection in addition to castration. The diagnosis, in 66 cases, was proved by microscopic examination. In the remainder of the series the diagnosis was made by rectal examination and by x-ray studies. All of these patients complained of symptoms referable to the act of urination, varying from frequency to complete retention. Forty-two patients complained of low-back pain and loss of weight. Hematuria was a symptom in only 7 patients. In 23 cases there was no clinical or x-ray evidence of any metastasis. Radical perineal prostatectomy was considered inadvisable, inasmuch as the disease was not confined within the capsule of the prostate, in all of the cases. Eighteen patients were found to have a normal serum phosphatase estimation prior to orchiectomy. In the remainder of the series there was an elevation of the serum phosphatase, and one was recorded at 155 units, using the King-Armstrong technic.

Following orchiectomy 18 patients were considered as complete clinical failures. In no instance was there any relief of pain and the progressive advancement of the disease was in no way altered. Stilbestrol was administered to these patients and found to be ineffective. It is interesting to note that in this group microscopic examination of tissue from the prostate revealed carcinoma of the undifferentiated type.

Fifty-seven patients showed immediate clinical results characterized by loss of all metastatic pain and general subjective improvement. Forty-three of this group must be considered as delayed failures, inasmuch as all again developed symptoms of advanced carcinoma of the prostate after intervals of from eight to thirty months. Examination revealed only partial regression of the disease in 21 of these cases. The microscopic examination of tissue from the prostate in this group revealed no definite histologic arrangement of the carcinoma. Areas of both the adenocarcinoma and undifferentiated type of carcinoma were the characteristic findings.

Of great interest is the fact that following orchiectomy 36 patients had complete clinical disappearance of the carcinoma. However, of this number only 14 were symptom-free and showed no evidence of any return of the disease after an interval of twelve to twenty-nine months. It is noteworthy that complete regression of the cancer occurred only in those cases in which microscopic examination of tissue from the prostate revealed a typical adenocarcinoma.

Serum phosphatase estimations were obtained for all patients following orchiectomy. These recordings were found to parallel the clinical features of each individual. In many patients a return of the carcinoma was signalled by a rise in the serum alkaline phosphatase before digital examination revealed any evidence of recurrent prostatic changes. Stilbestrol administered to this group of patients was found to be of value in the control of their symptoms but not of the disease.

Thus a summary of the cases of advanced carcinoma of the prostate treated by castration reveals results that may be divided into four groups:

1. Complete failure—This group is composed of cases of the undifferentiated type of carcinoma. Neither orchiectomy nor estrogens in any way alter the progress of the disease.

2. Partial failure—In this group there is a temporary relief of symptoms. Regression of the disease is not complete. The carcinoma shows no uniform arrangement.

3. Delayed failure—This group is composed of cases of well-differentiated adenocarcinoma. Orchiectomy is followed by a temporary but complete relief of all symptoms. The disappearance of the primary cancer and metastatic nodules, as proved by digital examination and serum phosphatase estimation, is not permanent.

4. A fourth group is added to include those cases having results similar to those in Group 3 and in which reactivation of the carcinoma has not occurred. The evidence is, however, that this group will be eliminated with the passage of time.

Thus, a review of treatment of advanced carcinoma of the prostate, by orchiectomy, reveals that while many cases are benefited, few, if any, are cured. There is no doubting the fact, however, that orchiectomy will produce a complete clinical regression of the disease in certain cases. In this connection, Barringer[8] states "that carcinoma of the prostate may remain enmeshed in fibrous tissue and be clinically suppressed for years before becoming activated." This opinion is substantiated in the following case.

Case Report

Case 1.—H. H., aged 70, had complete clinical and serologic disappearance of prostatic cancer following orchiectomy. Six months following castration he developed pneumonia and died. An autopsy was performed and microscopic examination of the prostate revealed cancer cells enmeshed in fibrous tissue.

Early recognition and complete removal of a carcinoma is generally recognized as the only hope of completely eradicating the disease.

In 1905, Dr Hugh H Young,[9] published his technic of radical perineal prostatectomy Lewis,[10] in reporting almost 50 per cent five-year cures in 115 cases of early prostatic cancer treated by Young and his staff, very definitely states that the disease can be cured Other exponents of this operative procedure, I know, have had comparable results

In view of the fact that it is becoming increasingly evident that certain cases of advanced carcinoma of the prostate completely regress following orchiectomy and later become activated why then not treat these cases like the bride, to "something old and something new?' Iodine administered preoperatively to patients with certain types of goiter has been proved to produce a regression of this disease We know that orchiectomy will produce a regression of certain cases of advanced cancer of the prostate Therefore, it is suggested that a radical perineal prostatectomy be performed on individuals in whom a carcinoma has been proved to have disappeared by digital examination and by the demonstration of normal acid and alkaline phosphatase blood levels

There is no doubting the great benefits many individuals are now enjoying as a result of orchiectomy One can only hope that a subsequent radical operation will prevent many of these patients from suffering the agonies of a return of the disease The test of time, of course, will prove the value of the suggested radical surgery and it is hoped at a later date results will be reported

Conclusions

Orchiectomy is a procedure of proved value in cases of advanced adenocarcinoma of the prostate, but few patients, if any, are cured It is of little or no value in cases of the undifferentiated type

It is suggested that a radical perineal prostatectomy may be of value in certain cases in which complete regression of the carcinoma has occurred as a result of orchiectomy and estrogen therapy

Discussion

Dr John K deVries, *New York City*—I have enjoyed all three of this afternoon's papers

Dr Heslin has re emphasized the need of thorough urologic study for the early recognition of upper urinary tract anomalies

Dr Davis has given us an important contribution in the control of certain ureteropelvic obstructions It will be interesting to find out whether ureters with such extensive injury regenerate completely or not

Because of the shortness of time I would like to spend it in the discussion of Dr Parlow's paper

Mark Curtis reported, in 1942, 27 cases of prostatic malignancy treated by castration at the New York Hospital He found 93 per cent immediate improvement and regression of skeletal metastases in 3 of 8 cases or 38 per cent

In reviewing these same cases two years later we have eliminated 2 cases because pathologic diagnosis failed to corroborate the diagnosis of carcinoma, but now, two years later, of 25 cases 11 are dead—45 per cent, 4 are unimproved or failing—16 per cent, 10 still show improvement—40 per cent Of the 10 patients still showing improvement 4 had perineal prostatectomy, and 6 had transurethral resection as well as castration

Of the 15 patients unimproved or dead 2 had no other operation Nine had transurethral resection, 4 had radical perineal prostatectomy as well as castration

Of the 23 cases of which pathologic diagnosis was made, 14 were listed as adenocarcinoma, 6 anaplastic, and 3 mixed types Three, or 50 per cent, of the anaplastic cases are among those still showing improvement, 6, or 42 per cent of the adenocarcinomas are among those still showing improvement One, or 33⅓ per cent, of the mixed types is among those still showing improvement

It has been my practice to do total perineals on all cases of prostatic cancer in which metastases cannot be demonstrated by x ray or elevation of phosphatase and to withhold castration for cases with advanced metastases with marked symptoms, as the last ace to be played

I believe, however, that Dr Parlow has a good idea which might be suitable for those cases without metastases

When skeletal metastases have occurred it is my impression that castration alone or combined with total prostatectomy is only palliative but should be used as the best method now available

Dr William J. Kennedy, *Gloversville New York*—Dr Davis has presented a unique and what appears to be a very versatile operation This operation depends for its success on the inherent ability of the ureter to repair itself when given proper splinting and drainage This principle has been used successfully for many years cystoscopically It is a

well-established fact that ureters injured during pelvic surgery will almost invariably heal if a catheter can be introduced above the injury, provided the catheter is permitted to remain *in situ* for a sufficiently long period. In these cases one can rarely demonstrate the extent of the ureteral laceration, but it is probable that some, at least, are fairly extensive. The fact that ureteral incisions, especially those parallel to the long axis of the ureter, heal readily without suturing makes possible the splendid results obtained by Dr. Davis.

During the past decade surgical procedures on the upper urinary tract have tended toward increasing conservatism. Hydronephrosis caused by ureteropelvic obstruction is being successfully managed by means of resection of the redundant pelvic tissue, transplantation of the ureter to avoid constricting vessels, and numerous other plastic procedures such as those described by Foley, Gibson, Young, and many others.

The Rammstedt operation has been effective in obstruction caused by stricture, but it is not suitable in instances where the wall of the ureter is thin, and therefore is of somewhat limited value. The plastic operations such as those advocated by Foley are of great value in the presence of hydronephrosis but are of no value whatever when an intrarenal pelvis is encountered.

The procedure presented by Dr. Davis offers a wide range of usefulness. It may be used in cases presenting hydronephrosis in any degree and is equally useful when an intrarenal pelvis is encountered. Since this procedure need not be confined to any particular portion of the ureter, it lends itself admirably to a wider range of use than does any other method. Dr. Davis has reported a case in which the ureter was strictured from a point just below the ureteropelvic junction to the midportion of the ureter. This was treated successfully by this method. The strictured portion of the ureter was opened, which left only a narrow ribbon of ureteral tissue. This was held in contact with an indwelling catheter by sutures. Complete regeneration of the ureter resulted. I know of no other procedure which could have accomplished the same results.

Persistent efforts to control prostatic cancer have been carried on steadily for many years but it is only within the past few years that any real progress has been made, and that, in the majority of cases, only a prolongation of life and some alleviation of pain. Suprapubic prostatectomy is inadequate; deep x-ray and radium are of only limited value.

With the advent of transurethral resection many hailed this method as a boon to the patient with prostatic cancer. For here at last was a method which was capable of keeping the prostatic urethra open and thus relieving the suffering caused by urinary retention. In many instances this was accomplished, but no case has ever been cured by this method. In 1905 Young described his radical perineal prostatectomy and presented a higher percentage of cures than could be claimed by advocates of any other method. To be effective the operation should be done before the capsule has been invaded, so only about 12 to 15 per cent of prostatic carcinomas are suitable for this operation.

About five years ago Huggins presented his work on the use of estrogens and castration. Immediate results were striking. Pain because of metastasis was relieved, often within forty-eight hours. Bone and lung metastases regressed. The gland became softer and less fixed and the serum phosphatase returned to normal. Patients who were apparently doomed regained their health and strength, and some were able to resume their former activities. After a variable period of time, however, practically all of them developed a return of their symptoms, metastasis recurred and extended, and the ultimate fatal termination ensued.

Dr. Parlow's method of handling cases of advanced carcinoma in which the capsule has been invaded is an interesting one. Most of us have been inclined to class this type of case as hopeless. Dr. Parlow, however, has not been content to adopt so passive an attitude. Following orchiectomy and the administration of estrogens he has found that some cases regressed to a degree which would permit a radical perineal prostatectomy to be done with some hope of success. What the ultimate results will be only time will tell. The immediate results obtained following orchiectomy and the administration of estrogens have been spectacular, to say the least. This has been especially true of the metastatic lesions. Unfortunately, however, results are usually not permanent. Metastatic lesions which have regressed recur and new ones develop. Since this process occurs in nearly all cases of distant metastasis, it is not unreasonable to assume that at least in some cases it may not also occur at the site of the primary lesion or in the tissue adjacent thereto. I believe, however, that the method suggested by Parlow offers the patient with advanced carcinoma of the prostate his best hope of survival.

I shall limit my remarks on Dr. Heslin's paper to the brief presentation of a few cases which illustrate the result of delayed diagnosis. The first case is that of a 10-year-old white boy who had suffered throughout most of his life from recurring attacks of fever, dysuria, urgency, and pyuria. His parents were urged by the family physician to permit a urologic investigation. Permission was refused and the child was not studied until his condition became grave, approximately two years later. At the time of his admission to the hospital, the patient was running a high temperature and the urine was foul and heavily loaded with pus. Cultures showed B. coli. The blood urea was 65; creatinine was 3.5. An intravenous phenolsulfonephthalein test showed no dye eliminated in two hours. Cystoscopy and pyelography were done. Urinary output became progressively more scant, blood urea and creatinine levels continued to rise, and the child died in coma twenty-five days after admission.

The second case is that of a 17-year-old boy who had never had any symptoms referable to his urinary tract, despite the fact that he had engaged to an unusual degree in contact athletics. One week

before admission, while playing basketball, he received a blow over the left loin from another player's knee Severe pain and some shock with subsequent hematuria ensued Retrograde pyelography showed the right kidney pelvis to be of normal size and contour, and 30 per cent of the phthalein was eliminated from this kidney in one-half hour No dye appeared from the left kidney during the same period The capacity of the left kidney was about 75 cc Nephrectomy was done

The third case is that of a 9 year old girl whose chief complaint was pain and tenderness in the right lower quadrant with fever, vomiting moderate leukocytosis, and rigidity She had been ill for twenty four hours before a physician was called On examination a mass was palpated which with the history, led to a diagnosis of acute appendicitis with abscess At operation a normal appendix was found and the mass was found to be retroperitoneal Subsequent urologic investigation revealed an ectopic kidney, the pelvis of which harbored B coli

The fourth case is that of a 7 year old girl who suffered recurring attacks of pain nausea, and vomiting, usually of about one week's duration Attacks recurred about every three weeks and were severe enough to confine her to bed Attacks were believed to be of gastrointestinal origin until she was seen by another physician, who discovered a mass in the upper quadrant A hydronephrotic kidney was found on cystoscopy

It is somewhat regrettable that Dr Heslin's paper could not have been presented before a group interested in general medicine, for it is a plea for early recognition of urinary tract disease which only the family physician is in a position to make

In conclusion, I wish to offer my congratulations to all the essayists for their very excellent papers

Dr Roy B Henline, *New York City*—Dr Parlow has presented some very interesting problems for consideration in the treatment of advanced carcinoma of the prostate According to his findings there is a marked difference in the response of cancer of the prostate to orchiectomy or stilbestrol injections, depending on the type of cancer present in the prostate His cases indicate that only adenocarcinoma of the prostate improves under this treatment and those prostates which present an undifferentiated type of cancer, or a mixed type, respond less favorably to orchiectomy This leads one to the assumption that the relationship of androgens to adenocarcinoma is fairly well established but that the same relationship to an undifferentiated carcinoma of the prostate is problematic

If this is true, a more careful pathologic examination of the tissue removed from patients with cancer of the prostate may aid us in evaluating the likely response to this form of therapy

Dr Parlow postulates the theory that radical perineal prostatectomy may be helpful in those patients who have been temporarily benefited by orchiectomy Cancer of the prostate, clinically confined within the prostatic capsule, is best treated by radical perineal prostatectomy Orchiectomy is usually done when there is either clinical or x ray evidence that the cancer has spread beyond the confines of the prostatic capsule He suggests that the subsequent removal of the prostate following orchiectomy in these cases, even with evidence of extension beyond the region to be surgically removed, may prolong the patient's life and inhibit the continued growth and spread of the cancer It may be possible that removal of the origin of the lesion by radical perineal prostatectomy may be beneficial in these cases, yet a group of cases would need to be followed over long periods of time before one could come to this conclusion We have followed this procedure in a number of cases in our department yet the time elapsing and the number of cases prevent us from evaluating our results at this time Any procedure which affords these patients prolonged comfortable life is worthy of consideration and Dr Parlow is to be commended for presenting this interesting paper

COUNTY MEDICAL SOCIETY LIFE MEMBERSHIPS AND ENDOWMENT FUNDS

In the July issue of the *Mississippi Valley Medical Journal*, Dr Harold Swanberg advocates the establishment of endowment funds and life membership plans in all but the smaller county medical societies "This plan affords the member an opportunity of paying his full dues during his most productive years and while his income is greatest, thus avoiding the burden of dues later in life"

Since life membership fees can be declared a profes- actual
omes
time
edical
up is
considerably less than the amount paid, since 27 to 57 per cent (depending on the surtax net income) represents tax savings If life membership fees are invested in war bonds and placed in an endowment fund it will further help the government finance the war, a patriotic undertaking of which every loyal American physician wants to be a part

Swanberg also states that "physicians, as a class, have not been generous with their contributions to medical organizations and it is high time efforts were made to correct this situation" He feels that "the physicia

ANOMALIES OF THE UPPER URINARY TRACT

JOHN E. HESLIN, M.D., and WILLIAM A. MILNER, M.D., Albany, New York

A FEW years ago, before this Section, we presented a paper on the conservation of renal tissue. The purpose of this discussion is to again call attention to the importance of anomalies of the urinary tract in the production of renal pathology and to make a plea for their early detection and surgical correction to accomplish renal conservation.

Intravenous urography, sulfa therapy, and improved plastic surgical procedures have been great contributions in this particular phase of urology, and the next few years should produce marked strides not only in the saving of kidney tissue, but in saving and prolonging, comfortably, the lives of patients.

In children especially is the early diagnosis of anomalies important. Relief of obstruction, before irreparable damage has been done, and the great restorative ability of renal tissue in children should lessen the number of cases now coming to us in which nephrectomy is the only procedure indicated.

Urologic investigation—at least urographic study by pediatricians and general practitioners of every case presenting obscure abdominal symptoms and recurrent cases of pyuria—must be carried out if we are to discover these cases early. The frequency of scars of abdominal incisions indicates that the surgeon should also take his place with those responsible for the overlooking of these lesions and resulting kidney loss.

When we consider the embryologic development of the upper urinary tract with the so-called ascent and rotation of the kidney to its normal position, we can see the opportunities for production of anomalies. Position, rotation, fusion, duplications, aberrant vessels, etc., can be traced to some stage in this development and account for the fact that there are probably more anomalies in the urinary tract than in any other system.

Gutierrez,[1] who is frequently quoted in discussions of the anomalies of the urinary tract, has given us an outline which we should keep in mind as we try to explain urologic pathology in the upper tract.

Incidence

Gutierrez has reported that 40 per cent of pathologic lesions in the ureters and kidneys are due to congenital anomalies. Campbell,[2] nine years ago, in reviewing his material, found 68.8 per cent of 282 cases of hydronephrosis in infants and children, secondary to upper tract anomalies; 30 per cent of 580 cases of persistent pyuria could be attributed to the presence of these conditions. Dees[3] reported that 135, or 9.6 per cent, of 1,410 consecutive patients showed congenital anomalies of the upper urinary tract. In 74.7 per cent of these the anomaly was the definite underlying cause of symptoms. In only 11.1 per cent was the anomaly without significance.

Culp and Hiebert,[4] in reviewing pyelographic studies in 747 Army patients with symptoms referable to the urinary tract, found 3.1 per cent with congenital anomalies. More than 50 per cent had infection, lithiasis, or hydronephrosis. They call attention to the fact that some anomalies cause symptoms in the absence of secondary pathology.

Mechanism

It is probable that *obstruction*—one of the fundamental factors in the production of urologic pathology—is here also the principal cause. Although a few cases of anomalous conditions are found on postmortem with no resulting damage, these cases are rare and we must assume that anomalies produce obstruction with resulting dilatation, back pressure, diminished kidney function, and the destruction of the parenchyma. Malposition, reduplication, and accessory bands and vessels account for much primary obstruction. Infection develops in this fertile soil and further progressive changes take place.

The progressive nature of the condition makes early diagnosis important and prophylactic treatment definitely indicated.

Symptoms

Unfortunately, no pathognomonic symptoms can be given and, in fact, marked progressive changes are frequently noted in the complete absence of symptoms. General abdominal symptoms with or without urinary tract symptoms may be the first noted, as surgical incisions would indicate. More and more urography is being used in vague abdominal complaints by the internist, pediatrician, and surgeon.

Urinary tract symptoms usually are associated with the development of infection. Pyelitis and cystitis, which fortunately, in this case, do not permanently clear up with any type of antiseptic, demand investigation and the anomaly is found.

Gastrointestinal symptoms, abdominal pain, and constipation, the so-called horseshoe kidney

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

syndrome, may make one suspicious of this in the absence of urinary tract symptoms Gutierrez reports this syndrome to be present in 96 per cent of his series of cases of horseshoe kidney

Diagnosis

The diagnosis of anomalies of the urinary tract depends, first, upon keeping their presence in mind On this basis, the use of the x ray and intravenous urography in cases of vague abdominal and back pain and recurrent urinary tract infections will uncover many cases

Complete urologic study, including cystoscopy and retrograde urography, will be necessary in most cases to secure the necessary information not only to govern the type of treatment indicated but also to guide the surgeon before and at the time of operation

Intravenous Urography—This most important phase of the diagnosis of these lesions frequently reveals the diagnosis, but unsatisfactory films must be supplemented with retrograde pyelograms

Frequent causes of poor intravenous films are (1) failure to dehydrate the patient, which allows too rapid excretion of the dye (2) failure to use abdominal pressure or Trendelenburg position to aid in retention of the dye, (3) in children, too small a dose of the dye We find that the subcutaneous injection of the adult dose in saline will give us satisfactory films in this so important class of cases

Misinterpretation of urographic films may lead to delay in proper diagnosis as revealed in a recent case An alert pediatrician, in caring for a child of three years, properly had urographic films made because of recurrent pyuria A typical obstructive type of bilateral hydronephrosis was wrongly diagnosed as polycystic disease, with its hopeless prognosis given Four years later, studies were repeated and retrograde pyelograms were made These films were submitted to an outstanding pediatric urologist, who reported obstructive hydronephrosis, and still the diagnosis of polycystic disease was insisted upon All types of antiseptics were used without results and this condition was allowed to progress for five more years, when we found bilateral congenital stricture at the pelvic outlet

Plastic operation has corrected the condition, and our hope is that the great recuperative power of the kidney in children may be sufficient to allow him a normal span of life

It is difficult to estimate the true kidney function in these cases of long standing hydronephrosis We cannot rely upon the poor excretion in an intravenous pyelogram or, in fact, upon the phthalein output at the time of cystoscopy Continued drainage may produce as startling improvement in function as we see in prostate cases placed upon continuous drainage Consideration of this fact may conserve a kidney which otherwise might appear to require nephrectomy

Hydronephrosis associated with aberrant vessels may show a typical defect suggesting this causative factor, and the relation of the ureters to the pelvis may make one suspicious of high insertion of the ureter However, the large pelvis may entirely mask the true condition present, and we agree with Henline and Menning[5] that an accurate diagnosis must, in most cases, be made at the operating table

Gutierrez has devised the pyelographic triangle as a most important sign in the diagnosis of horseshoe kidney A flat plate may show an altered position of the lower poles of the kidney or the isthmus joining the poles The characteristic course of the ureters, giving the so-called "flower vase" appearance, is also diagnostic

To meet this challenge of a greater number of anomalies in the urinary tract we have a most efficient diagnostic armamentarium, and its use is all that is necessary to unmask most of these silent, progressive, destructive processes

Treatment

Although we do see an occasional case of upper urinary tract anomaly going on throughout life without symptoms or progression, this cannot be accepted as a basis for all treatment

Age of patient, type of lesion, associated pathology and stage in its progress will influence our handling of each case

Anomalies with no resulting pathology demand no treatment If discovered early in life our responsibility demands urologic study at intervals to note any early change Cases with minor changes resulting from anomalies may be observed at intervals and their response to internal medication and instrumental procedures may be noted

The presence of attacks of pain, persistent and recurrent pyuria, or progressive hydronephrosis demands correction We are, then, dealing with a progressive lesion and we are not justified in carrying these patients on with palliative measures Removal of the obstructing factor may require a simple procedure or some complicated plastic operation The simple freeing of bands of fibrous tissue or small polar aberrant vessels may save the kidney Henline and Menning have called attention to the presence of associated pathology at the ureteropelvic junction in these latter cases

Plastic surgical procedures necessary to relieve obstruction are not within the scope of this paper.

The type of operation must be selected to fit the particular problem found at the time of exploration.

Pre- and postoperative sulfa therapy has greatly added to our success and has given us a greater number of cases where operation is indicated.

The contributions of Hinman, Young, Deblet, Foley, Schwartz, and others have provided several technics, each having its place in the mechanical handling of the ureteropelvic junction changes.

Splinting of the ureter, use of fine sutures, careful coaptation of the edges, nephrostomy drainage for varying periods of time, are probably the most important technical points leading to a successful result.

Summary

1. Anomalies of the upper urinary tract are frequent, usually progressive, and destroy kidney tissue.

2. Vague abdominal symptoms and persistent and recurrent pyuria demand urographic and urologic investigation.

3. Satisfactory surgical procedures can be expected to relieve in a large proportion of cases.

4. A plea is made for the early recognition and surgical correction of these anomalies.

SHAW VERSUS MEDICINE

"He who can, does; he who cannot, teaches," wrote Mr. Bernard Shaw in his revolutionary days, and for the past sixty years he has been teaching and preaching at a good-humoured English public who have richly rewarded him for the amusement he has provided them. For the past thirty-eight years hundreds, perhaps thousands, of doctors have cheerfully handed in their money at the box office in order to get a good laugh out of *The Doctor's Dilemma*, quite unperturbed by the attack made by Shaw upon the medical profession, because it was very plain that he did not understand the nature of a doctor's work. Whatever else he has learnt in order to try to teach others, he seems not to have learnt one lesson—that of humility; and it is the absence of this quality in his recent book which has dismayed some of his reviewers. Since the publication of *The Doctor's Dilemma* in 1906 Mr. Shaw seems to have confirmed himself in his own ignorance of medical matters, and now abuses the great position he holds in the public life of his country by misrepresenting facts. "Men," he writes, "have submitted to castration . . . . but compulsion of everybody willynilly to dangerous blood poisoning repeated for every virus discoverable by the new electron microscope, to sterilization, to extirpation of the uvula and tonsils, to birth delivery by the cesarean operation, to excision of several folds of the bowel and of the entire appendix, to treatment of syphilis and malaria by doses of mercury and arsenic, iodine, and quinine, all of which have been advocated by eminent physicians and surgeons, and some of them legally enforced to-day. . . . "

This suggestion of compulsion is not true of medicine in this country. He says of the modern treatment of venereal disease, presumably meaning the treatment of gonorrhea by sulfonamides and penicillin, "There is the gravest doubt as to whether the prescribed treatment of venereal disease is not mischievously mistaken." Of salvarsan he observes, "The truth was that it combined mercury with arsenic"; the truth is that mercury does not enter into the composition of salvarsan. Mr. Shaw goes on, "When, as in the case of syphilis, the suppressive agent is a malignant poison, it is strongly held in certain quarters that the terrible secondary and tertiary recurrences of the worst symptoms are not the disease at all but the specific effect of the poisons with which it has been treated." Of surgeons he observes that "scepticism as to the utility of drugs is shared by surgeons. They use drugs only to produce temporary insensibility to pain." This remark shows the extent of Mr. Shaw's ignorance of modern surgery.

Mr. Shaw brings up again his old bugbears of vaccination and vivisection, and, as he apparently wishes to be seriously considered as a statistician, we have invited the foremost medical statistician of the day, Prof. Major Greenwood, to examine the statistical exercises of an amateur (see page 570, October 8 issue). Some insight into the emotional basis of Mr. Shaw's ratiocination is provided by his statement, "Of all legalized tyrannies none is more unbearable than those which lay violent hands on us and our children and inject poisons into our veins or thrust them down our throats." Mr. Shaw thinks that Isaac Newton wrote nonsense when he passed from mathematics to theology; it is possible that Mr. Shaw is not intellectually so much greater than Newton, that, when he puts playwriting aside and turns to pathology, he can write good sense.—*Editorial, British M. J., Oct. 28, 1944*

THE SIGNIFICANCE OF HYPERGLYCEMIA IN MYOCARDIAL INFARCTION

EMANUEL GOLDBERGER, M D , JOSEPH ALESIO, M D , and FANYA WOLL, New York City

(From the Department of Medicine Lincoln Hospital, New York, Dr Leander H Shearer, Director)

ALTHOUGH it has often been reported that during the acute attacks of myocardial infarction, transient glycosuria and hyperglycemia appear,[1–6] the significance and interpretation of this data is still uncertain, especially as to whether this hyperglycemia is to be considered a sign of latent or incipient diabetes mellitus

Furthermore, there does not seem to have been any attempt made to follow up individual patients over any long period of time We therefore felt that study of blood sugar curves in individual patients, not only during the period of acute infarction but during the course of their convalescence and rehabilitation, might be of value

Method

In our study of sugar metabolism we made use of the Exton and Rose oral one-hour, two-dose glucose tolerance test[7] Briefly, the test is performed as follows

1 One hundred grams of glucose is dissolved in 650 cc of water and divided into two equal parts, each containing 50 Gm of glucose

2 Following an overnight fast, the bladder is emptied and a sample of urine is saved as a "fasting specimen"

3 Blood is then drawn for a "fasting blood sugar" determination, and the first dose of glucose is given

4 In one-half hour, a second specimen of urine and of blood is collected, and the patient is given the second dose of glucose

5 Thirty minutes after this, a third specimen of urine and of blood is collected

Concerning the interpretation of the results, we used the following criteria established by Matthews, Magath, and Berkson[8]

1 If the fasting blood sugar level is over 90 mg , diabetes may be suspected

2 A half-hour level of more than 142 mg indicates probable diabetes

3 An hour level of 158 mg or more indicates diabetes If the value is over 180 mg diabetes is definite

4 In nondiabetics the hour level is lower than the half hour level

Material

Thirty-eight tests were performed on 14 patients with myocardial infarction, selected by chance, over a period extending in certain cases up to thirteen months All patients had been hospitalized for acute myocardial infarction The diagnosis was determined not only clinically but by means of serial electrocardiograms, sedimentation rates, blood counts, etc Many of the patients are still being observed by us in the cardiac clinic of the hospital In none of the patients was there either a history or evidence suggestive of diabetes, and routine urine analyses were always negative for sugar

In all but 3 of the patients at least two glucose tolerance tests were done

Results

The data are tabulated in Table 1 Using the criteria described above, of the total series of 14 cases, 6 presented definite evidence of diabetes, 4 were abnormal, and 4 were normal Of the 11 patients who had blood determinations done within two weeks after the attack, 7 were normal and 4 were abnormal If the first 6 cases presenting the "diabetic sugar curve" are further analyzed, the results become more significant

Case Reports

Case 1 —This patient did not begin to show abnormal values until six weeks after the attack, after which time the sugar values became more and more abnormal, until at the end of seven months, they were frankly diabetic Thirteen months after the infarction the glucose tolerance curve was still diabetic

Case 2 —This patient had a normal sugar curve at the end of ten days, it was slightly abnormal after twenty one days, and at the end of six months was diabetic Toward the end of a year after the initial attack, the glucose tolerance curve though not diabetic, was still slightly abnormal (the hour value was higher than the half-hour reading)

Case 3 —The patient was normal three days after the attack but had a diabetic tolerance after five months, and at eight months was still abnormal A year after the attack, although the actual readings were within normal, again the hour reading was higher than the half hour level

Case 4 —The sugar curve was normal at the end of one month, but the patient had a diabetic tolerance after two and a half months

Case 5 —The patient presented diabetic curves after three weeks, after three months, and after eight and a half months

Case 6 —This patient had a diabetic curve at the end of ten days, but by four and a half months, although the values were within normal, again the hour level was higher than the half hour reading

2. Supply oxygen to the lungs rapidly.— There are four methods of doing this:

(*a*) Mouth-to-mouth breathing. This is a most useful method, inasmuch as no apparatus is required and the means of its accomplishment are always at hand. It is a valuable method and has saved many lives, particularly in infants. It is occasionally destructive, since the overenthusiastic resuscitator is liable to exert more intrapulmonic pressure than the lung can withstand. It is important to remember that a safe intrapulmonic pressure in infants is 10–15 mm. of mercury and in adults, 40–50 mm. of mercury. Wilson[8] has stated, "The lung tissue cannot, itself, be adequately aerated (inflated) even by pressures high enough to be injurious or destructive." Henderson[9] answered, "Intratracheal insufflation is not done for the purpose of inflating the lungs. It should not inflate, and if properly done it cannot inflate. It merely supplies oxygen so deep in the respiratory tract that the blood is oxygenated without any respiratory movement of the chest." In applying mouth-to-mouth resuscitation, therefore, only a moderate pressure should be exerted, as harmful effects may ensue otherwise.

(*b*) Manual methods. The Schaeffer prone-pressure method is accepted today as the most easily applied and most efficient of the various manual methods. In recent years there has been a great impetus given to the teaching of this method to various groups, particularly first-aid classes, and many lay people have become skilled in its use. It is an essential part of the physician's armamentarium that he be skilled, too, in its application. Other methods, *viz.*, Silvester arm-abducting method, Neilson prone pressure, Eve rocking, and Thomson lifting methods have found much favor among certain groups, particularly the Eve rocking method, which is very popular in the British armed services.

(*c*) Mechanical methods. There are many and varied types of mechanical resuscitators in the field, the very number of which indicates that no one type is entirely satisfactory. Any mechanical resuscitator should fulfill the three requirements as stated:

1. Insure the patency of the airway,
2. Supply oxygen to the lungs rapidly, and
3. Do this under measured pressure.

The only mechanical resuscitator that fulfills these three requirements is one that follows the principle of Meltzer and Flagg in the use of a laryngoscope and the employment of aspiration and intubation of the larynx and trachea as its primary *modus operandi*. Any other mechanical aid that neglects the first principle (insure the patency of the airway) is not worthy of classification as a resuscitator; these are merely inhalators. A large percentage of asphyxias are caused by obstructions in the upper respiratory tract, hence a mere inhalator which supplies oxygen only to the mouth and not deep in the respiratory tree is useless as such, hence, pneumatologists are skilled in visualizing the larynx and introducing tubes into the trachea after aspiration of the passage. The frequent use of "suck-and-blow" apparatus has been instrumental in popularizing this type of machine[10] but it is useless when the cause of the asphyxia is obstruction of the airway. More recent experimental work has demonstrated that "suck-and-blow" is, in itself, effective when the airway is patent, even using inert (asphyxiating) gases.[11] The pneumatologist must determine the method of resuscitation and the type of resuscitator to be used (if at all) on each case and to remember that Henderson has said, "Prolonged, forcible, 'suck-and-blow' artificial respiration may cause injury to the lungs, shock, and death."[12] If the asphyxia is not caused by mechanical obstruction, then the various "suck-and-blow" resuscitators may prove useful. This can be accomplished without the use of high-priced instruments by merely employing the rubber bag of the anesthetic machine and rhythmically compressing it with the hand. Hand pressure, however, should be so performed as to avoid pressures that are excessive. Mechanical "suck-and-blow" resuscitators may perform this function and without danger of overdistention of the alveoli if they are based upon the action of pistons which are so calibrated as not to exceed 40–50 mm. of mercury intrapulmonic pressure for the adult, and 10–15 mm. for the infant. In the latter class may be placed the E and J resuscitator and the Emerson resuscitator. The Kreiselman resuscitator has also found favor. The Drinker resuscitator (the so-called iron lung) is a very valuable machine for use in chronic or long-standing asphyxias, such as in poliomyelitis or Landray's paralysis. It should be available in every community.

(*d*) Drug treatment. The analeptics usually employed are metrazol, coramine, alphalobeline, and lobeline hydrochloride. They occasionally prove valuable when used in conjunction with mechanical or manual methods. They are useless in asphyxia if used alone. Picrotoxin is of use in the treatment of barbiturate poisoning. It should be borne in mind in using these drugs that they are convulsants and if used improperly, or to excess, may result in a convulsive state and consequent irreparable damage to the physical status of the patient.

(*e*) Supportive measures. The pneumatologist employs heat as one of his most effective aids in resuscitation. The heat can be applied in the

THE SIGNIFICANCE OF HYPERGLYCEMIA IN MYOCARDIAL INFARCTION

EMANUEL GOLDBERGER, M.D., JOSEPH ALESIO, M.D., and FANYA WOLL, New York City

(From the Department of Medicine, Lincoln Hospital, New York, Dr. Leander H. Shearer, Director)

ALTHOUGH it has often been reported that during the acute attacks of myocardial infarction, transient glycosuria and hyperglycemia appear,[1-6] the significance and interpretation of this data is still uncertain, especially as to whether this hyperglycemia is to be considered a sign of latent or incipient diabetes mellitus.

Furthermore, there does not seem to have been any attempt made to follow up individual patients over any long period of time. We therefore felt that study of blood-sugar curves in individual patients, not only during the period of acute infarction but during the course of their convalescence and rehabilitation, might be of value.

Method

In our study of sugar metabolism we made use of the Exton and Rose oral one-hour, two-dose glucose tolerance test.[7] Briefly, the test is performed as follows:

1. One hundred grams of glucose is dissolved in 650 cc. of water and divided into two equal parts, each containing 50 Gm. of glucose.
2. Following an overnight fast, the bladder is emptied and a sample of urine is saved as a "fasting specimen."
3. Blood is then drawn for a "fasting blood sugar" determination, and the first dose of glucose is given.
4. In one-half hour, a second specimen of urine and of blood is collected, and the patient is given the second dose of glucose.
5. Thirty minutes after this, a third specimen of urine and of blood is collected.

Concerning the interpretation of the results, we used the following criteria established by Matthews, Magath, and Berkson:[8]

1. If the fasting blood sugar level is over 90 mg., diabetes may be suspected.
2. A half-hour level of more than 142 mg. indicates probable diabetes.
3. An hour level of 158 mg. or more indicates diabetes. If the value is over 180 mg. diabetes is definite.
4. In nondiabetics, the hour level is lower than the half-hour level.

Material

Thirty-eight tests were performed on 14 patients with myocardial infarction, selected by chance, over a period extending in certain cases up to thirteen months. All patients had been hospitalized for acute myocardial infarction. The diagnosis was determined not only clinically but by means of serial electrocardiograms, sedimentation rates, blood counts, etc. Many of the patients are still being observed by us in the cardiac clinic of the hospital. In none of the patients was there either a history or evidence suggestive of diabetes, and routine urine analyses were always negative for sugar.

In all but 3 of the patients at least two glucose tolerance tests were done.

Results

The data are tabulated in Table 1. Using the criteria described above, of the total series of 14 cases, 6 presented definite evidence of diabetes, 4 were abnormal, and 4 were normal. Of the 11 patients who had blood determinations done within two weeks after the attack, 7 were normal and 4 were abnormal. If the first 6 cases presenting the "diabetic sugar curve" are further analyzed, the results become more significant.

Case Reports

Case 1.—This patient did not begin to show abnormal values until six weeks after the attack, after which time the sugar values became more and more abnormal, until, at the end of seven months, they were frankly diabetic. Thirteen months after the infarction the glucose tolerance curve was still diabetic.

Case 2.—This patient had a normal sugar curve at the end of ten days; it was slightly abnormal after twenty-one days, and at the end of six months was diabetic. Toward the end of a year after the initial attack, the glucose tolerance curve, though not diabetic, was still slightly abnormal (the hour value was higher than the half-hour reading).

Case 3.—The patient was normal three days after the attack but had a diabetic tolerance after five months, and at eight months was still abnormal. A year after the attack, although the actual readings were within normal, again the hour reading was higher than the half-hour level.

Case 4.—The sugar curve was normal at the end of one month, but the patient had a diabetic tolerance after two and a half months.

Case 5.—The patient presented diabetic curves after three weeks, after three months, and after eight and a half months.

Case 6.—This patient had a diabetic curve at the end of ten days, but by four and a half months, although the values were within normal, again the hour level was higher than the half-hour reading.

The type of operation must be selected to fit the particular problem found at the time of exploration.

Pre- and postoperative sulfa therapy has greatly added to our success and has given us a greater number of cases where operation is indicated.

The contributions of Hinman, Young, Deblet, Foley, Schwartz, and others have provided several technics, each having its place in the mechanical handling of the ureteropelvic junction changes.

Splinting of the ureter, use of fine sutures, careful coaptation of the edges, nephrostomy drainage for varying periods of time, are probably the most important technical points leading to a successful result.

Summary

1. Anomalies of the upper urinary tract are frequent, usually progressive, and destroy kidney tissue.

2. Vague abdominal symptoms and persistent and recurrent pyuria demand urographic and urologic investigation.

3. Satisfactory surgical procedures can be expected to relieve in a large proportion of cases.

4. A plea is made for the early recognition and surgical correction of these anomalies.

SHAW VERSUS MEDICINE

"He who can, does; he who cannot, teaches," wrote Mr. Bernard Shaw in his revolutionary days, and for the past sixty years he has been teaching and preaching at a good-humoured English public who have richly rewarded him for the amusement he has provided them. For the past thirty-eight years hundreds, perhaps thousands, of doctors have cheerfully handed in their money at the box office in order to get a good laugh out of *The Doctor's Dilemma*, quite unperturbed by the attack made by Shaw upon the medical profession, because it was very plain that he did not understand the nature of a doctor's work. Whatever else he has learnt in order to try to teach others, he seems not to have learnt one lesson—that of humility; and it is the absence of this quality in his recent book which has dismayed some of his reviewers. Since the publication of *The Doctor's Dilemma* in 1906 Mr. Shaw seems to have confirmed himself in his own ignorance of medical matters, and now abuses the great position he holds in the public life of his country by misrepresenting facts. "Men," he writes, "have submitted to castration . . . . but compulsion of everybody willynilly to dangerous blood poisoning repeated for every virus discoverable by the new electron microscope, to sterilization, to extirpation of the uvula and tonsils, to birth delivery by the cesarean operation, to excision of several folds of the bowel and of the entire appendix, to treatment of syphilis and malaria by doses of mercury and arsenic, iodine, and quinine, all of which have been advocated by eminent physicians and surgeons, and some of them legally enforced to-day. . . . "

This suggestion of compulsion is not true of medicine in this country. He says of the modern treatment of venereal disease, presumably meaning the treatment of gonorrhea by sulfonamides and penicillin, "There is the gravest doubt as to whether the prescribed treatment of venereal disease is not mischievously mistaken." Of salvarsan he observes, "The truth was that it combined mercury with arsenic"; the truth is that mercury does not enter into the composition of salvarsan. Mr. Shaw goes on, "When, as in the case of syphilis, the suppressive agent is a malignant poison, it is strongly held in certain quarters that the terrible secondary and tertiary recurrences of the worst symptoms are not the disease at all but the specific effect of the poisons with which it has been treated." Of surgeons he observes that "scepticism as to the utility of drugs is shared by surgeons. They use drugs only to produce temporary insensibility to pain." This remark shows the extent of Mr. Shaw's ignorance of modern surgery.

Mr. Shaw brings up again his old bugbears of vaccination and vivisection, and, as he apparently wishes to be seriously considered as a statistician, we have invited the foremost medical statistician of the day, Prof. Major Greenwood, to examine the statistical exercises of an amateur (see page 570, October 8 issue). Some insight into the emotional basis of Mr. Shaw's ratiocination is provided by his statement, "Of all legalized tyrannies none is more unbearable than those which lay violent hands on us and our children and inject poisons into our veins or thrust them down our throats." Mr. Shaw thinks that Isaac Newton wrote nonsense when he passed from mathematics to theology; it is possible that Mr. Shaw is not intellectually so much greater than Newton, that, when he puts playwriting aside and turns to pathology, he can write good sense.—*Editorial, British M. J., Oct. 28, 1944*

a precipitating factor to make a latent diabetes manifest [1 3]

In view of the fact that many of our cases tended to show signs of abnormal sugar metabolism long after the acute signs of infarction had disappeared, we cannot accept the concept that the hyperglycemia is a temporary phenomenon, and thus are forced to discard the first and second hypotheses Before discussing the concept that these changes are a manifestation of diabetes, it would be well to consider the effect of hypertension itself as a cause of hyperglycemia

It is recognized that conditions other than diabetes are capable of causing abnormal glucose tolerance curves, such as endocrine disturbances and liver disease [10] Among other causes have been described nephritis[11–13] and hypertension [9]

None of our patients gave evidence of nephritis (either on the basis of history or physical examination or from urinary findings), but 6 had evidence of hypertension However, critical studies of blood sugar levels in hypertension have cast doubt upon the idea that it can be a cause of abnormal sugar metabolism [11–13] Furthermore, O Hare, who, for example, was one of those who described abnormal sugar values in cases of hypertension, felt that some of his patients had sugar values which could be considered diabetic

The general tendency of the glucose tolerance tests to become more and more abnormal over a period of time makes us feel that these patients have latent diabetes The fact that at the end of a year Cases 2 and 4 had returned to values which could be interpreted as within normal limits only serves to accentuate the chronic nature of the disturbance in sugar metabolism which was present

Signs of abnormal cholesterol metabolism in three of the patients are a further indication of the disturbed metabolism Finally, the high incidence of clinical diabetes in relation to coronary artery disease has long been recognized [4 14]

As to whether the activation of the diabetes was the cause of the infarction, or whether the disturbed circulatory mechanisms subsequent to the infarction effected changes in an already arteriosclerotic pancreas (or other organ systems through which blood sugar control is mediated), as some have thought[1 3], cannot be answered at this time

Nor are we able to state, nor do we wish to imply that all patients with myocardial infarction are potentially or latently diabetic In this respect, 3 of our patients (Cases 11, 12, and 14) had evidence of previous infarctions, but in two of these, the sugar values were normal over the period of time they were studied

We feel, however, that the data in this paper warrant the following conclusions

1 Hyperglycemia may or may not be present soon after an attack of myocardial infarction

2 Its appearance may be delayed until months later

3 The hyperglycemia, when present in relation to myocardial infarction, may be considered as a sign of latent diabetes

4 As a corollary, a percentage of patients with myocardial infarction may be considered potential candidates for diabetes mellitus in spite of the fact that they may have manifested no such tendency previous to the infarction (in so far as can be determined) *

Summary

Fourteen patients with myocardial infarction were studied for signs of abnormal sugar metabolism by means of the Exton and Rose glucose-tolerance test, over a period extending in some cases to thirteen months Of 11 who had a test taken within the first two weeks after the infarction, 7 of these were normal and only 4 abnormal Five patients who had normal values during the acute phase of their illness became progressively more and more abnormal after a period of months, finally reaching diabetic values

It was therefore felt that while hyperglycemia may or may not be present during an acute attack of myocardial infarction, or have its presence delayed until late in the period of convalescence, when it is present it may be regarded as a sign of latent diabetes mellitus Finally, the possibility that patients with myocardial infarction may develop signs of diabetes later is not negligible

* All patients were admitted within twenty-four hours after their attack. Therefore, the days the blood chemistries were taken correspond well to the interval from the onset of the infarction.

† + signs indicate glycosuria.

‡ After recovery from the initial shock within twenty-four hours, the blood pressure levels tended to remain fairly constant, and so only the highest reading obtained is given. No correlation was found between the blood pressure and the glucose tolerance curve.

To analyse the cases with less marked abnormalities: Cases 7 and 8 did not show abnormalities until after discharge from the hospital, whereas Case 9 was abnormal soon after the attack and later. In Case 14, the significance of the abnormal values six days after the infarction cannot be evaluated.

It is interesting to note that 3 patients (Cases 2, 4, 10) also exhibited evidence of disturbed cholesterol metabolism.

Glycosuria, during the test, was inconstant.

Discussion

It has generally been accepted that the glycosuria and hyperglycemia seen after myocardial infarction is a temporary condition.[1–6] Our series of cases, although small, is significant in that it tends to cast doubt upon the validity of this concept. Of 11 cases in which the test was done within two weeks after the attack, normal sugar curves were obtained in 7, abnormal in only 4. Furthermore, in 5 cases, it was only after the patient had been observed for a long period of time that the glucose tolerance test became abnormal, reaching actual diabetic values in 4 cases of this subgroup (Cases 1, 2, 3, and 4).

The theories which have been proposed to explain the hyperglycemia after myocardial infarction may be summarized as follows:

1. The hyperglycemia is caused by adrenal stimulation which is caused by the initial shock and anoxemia. Eppinger[2] has described it as caused by the outpouring of epinephrine which results as a consequence of the absorption of products of protein disturbance from the infarct.

2. The hyperglycemia has been described as a disturbance of the vegetative centers of the brain, resulting from the circulatory disturbances secondary to the infarct.[5]

3. The hyperglycemia has been considered to be caused by a coexistent hypertension.[9] With this concept, myocardial infarction need not be considered as a cause.

4. The hyperglycemia has been considered as a manifestation of diabetes, the infarct acting as

a precipitating factor to make a latent diabetes manifest [1 3]

In view of the fact that many of our cases tended to show signs of abnormal sugar metabolism long after the acute signs of infarction had disappeared, we cannot accept the concept that the hyperglycemia is a temporary phenomenon, and thus are forced to discard the first and second hypotheses Before discussing the concept that these changes are a manifestation of diabetes, it would be well to consider the effect of hypertension itself as a cause of hyperglycemia

It is recognized that conditions other than diabetes are capable of causing abnormal glucose tolerance curves, such as endocrine disturbances and liver disease [10] Among other causes have been described nephritis[11 12] and hypertension [9]

None of our patients gave evidence of nephritis (either on the basis of history or physical examination or from urinary findings), but 6 had evidence of hypertension However, critical studies of blood sugar levels in hypertension have cast doubt upon the idea that it can be a cause of abnormal sugar metabolism [11–13] Furthermore, O Hare, who, for example, was one of those who described abnormal sugar values in cases of hypertension, felt that some of his patients had sugar values which could be considered diabetic

The general tendency of the glucose tolerance tests to become more and more abnormal over a period of time makes us feel that these patients have latent diabetes The fact that at the end of a year Cases 2 and 4 had returned to values which could be interpreted as within normal limits only serves to accentuate the chronic nature of the disturbance in sugar metabolism which was present

Signs of abnormal cholesterol metabolism in three of the patients are a further indication of the disturbed metabolism Finally, the high incidence of clinical diabetes in relation to coronary artery disease has long been recognized [4 14]

As to whether the activation of the diabetes was the cause of the infarction, or whether the disturbed circulatory mechanisms subsequent to the infarction effected changes in an already arteriosclerotic pancreas (or other organ systems through which blood sugar control is mediated), as some have thought[1 3], cannot be answered at this time

Nor are we able to state, nor do we wish to imply that all patients with myocardial infarction are potentially or latently diabetic In this respect, 3 of our patients (Cases 11, 12, and 14) had evidence of previous infarctions, but in two of these, the sugar values were normal over the period of time they were studied

We feel, however, that the data in this paper warrant the following conclusions

1 Hyperglycemia may or may not be present soon after an attack of myocardial infarction

2 Its appearance may be delayed until months later

3 The hyperglycemia, when present in relation to myocardial infarction, may be considered as a sign of latent diabetes

4 As a corollary, a percentage of patients with myocardial infarction may be considered potential candidates for diabetes mellitus in spite of the fact that they may have manifested no such tendency previous to the infarction (*in so far as can be determined*) *

Summary

Fourteen patients with myocardial infarction were studied for signs of abnormal sugar metabolism by means of the Exton and Rose glucose-tolerance test, over a period extending in some cases to thirteen months Of 11 who had a test taken within the first two weeks after the infarction, 7 of these were normal and only 4 abnormal Five patients who had normal values during the acute phase of their illness became progressively more and more abnormal after a period of months, finally reaching diabetic values

It was therefore felt that while hyperglycemia may or may not be present during an acute attack of myocardial infarction, or have its presence delayed until late in the period of convalescence, when it is present it may be regarded as a sign of latent diabetes mellitus Finally, the possibility that patients with myocardial infarction may develop signs of diabetes later is not negligible

* Against the possible argument that the low blood-sugar values during the stage of the acute infarct were caused by depression of previously high and abnormal values our control studies show that the glucose tolerance curves of known diabetics who develop an infarct remain high and abnormal

PREVENTION OF HEMORRHAGIC ANEMIA AFTER BLOOD DONATION IN NORMAL ADULTS

SHEPARD SHAPIRO, M.D., C. P. SEGARD, M.D., and ESTELLE N. TABACHNICK, B.A., New York City

THERE is still some disagreement in the literature on the role of copper in the mechanism of hemoglobin synthesis. In experimentally induced anemias in animals and in certain of the childhood anemias it appears to have been demonstrated adequately that copper acts as a catalyst in the conversion of stored iron into hemoglobin iron.[1–3] In the case of adults such data are equivocal, due principally to the studies having been vitiated by virtue of a multiplicity of factors. This is especially true when disease processes were present which might have influenced absorption and utilization of the metals.

An opportunity presented itself to obtain data in normal adults, healthy except for the presence of acute hemorrhagic anemia caused by the sudden withdrawal of 500 ml. of blood. Our subjects were volunteers who donated blood every two months to an organization supplying plasma to the armed forces. It is the purpose of this paper to report the results of an investigation of the hematopoietic effects of iron alone and iron plus copper in this type of hemorrhagic anemia.

Method

Fifteen volunteers, varying in ages between 22 and 50 years, agreed to cooperate in this study. All were in good health and all were "white collar" workers engaged in either office or laboratory occupations. The food intake was adequate in each case and each agreed to adhere to his regular mode of living, including dietary habits, during the interval of the study. The investigation extended over three blood-donation periods. The first was used as a control period in which the subjects were allowed to recover without medication. During the second and third donation periods, the diet was supplemented by either of two medications selected for the comparison.

These subjects reported to our private laboratory at frequent intervals for blood examinations. Complete blood counts, including hemoglobin and hematocrit determinations, were made during a short control period prior to the blood donation and were repeated twenty-four hours after the donation and once weekly thereafter until the blood values were restored to the predonation level. Hemoglobin determinations, however, were made three or four times each week during the first two weeks. All the determinations were made by the same person (E. N. T.). The hemoglobin was determined by the acid hematin method, using a photoelectric colorimeter calibrated so that 14.5 Gm. = 100 per cent.

Control Donation Period

Eleven of the 15 subjects showed precipitous depressions in the hemoglobin content of the blood, averaging 14 per cent, following blood donation. These 11, continuing their usual dietary habits and without iron supplementation, required twenty-six to forty-seven days to recover their predonation levels. The remaining 4 showed only slight anemia and their hemoglobin values were restored to their respective normal levels in fifteen to nineteen days. The average time required was thirty days. The mean values of the entire series are shown in Chart 1.

Medication with Hematopoietic Agents

Of the original group of 15, 9 continued in the second phase of the study on hemoglobin regeneration. At least a two-months' period was allowed to elapse between blood donations. Commencing two days prior to the second donation and continuing daily until the blood values equalled or approximated closely the predonation levels, the subjects were given medications containing either iron alone or iron plus copper. The iron-containing medication was administered in the form of enteric-coated tablets of ferrous sulfate. The daily dose calculated as iron was 0.21 Gm. Iron plus copper was administered in the form of tablets containing, among other ingredients, iron and copper sulfates. The amount of iron and copper administered daily was 0.50 Gm. and 0.0150 Gm. respectively, the proportion being 1 to 33.* The tablets were taken with or immediately after meals. This was emphasized because it proved to be a means of avoiding gastric disturbance.

* Each Licuron-B tablet contains: liver fraction from 10 Gm. (155 grains) of liver; ferrous sulfate, dried, 0.084 Gm.; copper sulfate, 0.0025 Gm.; thiamine hydrochloride, 0.335 mg.; riboflavin, 0.623 mg.; and niacinamide, 3.32 mg. This medication was selected for the study because it had been found to be better tolerated than other medications of this kind. The possible importance of the other factors, especially the liver fraction, is being determined by an additional study and will be reported in a subsequent communication.

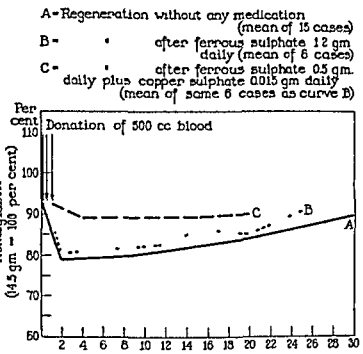

CHART 1 Illustrating blood regeneration after induction of hemorrhagic anemia by donation of 500 cc of blood

Curve (A) = no medication
(B) = iron therapy alone
(C) = copper plus-iron therapy

After the required two-month interval a third blood donation was made by these volunteers For the third donation period the medication was alternated so that the subject receiving the iron-containing tablets during the second donation period now received the tablets containing iron plus copper, and vice versa

Of the 9 *remaining subjects 6 completed the* series of donations Three were compelled to withdraw either because of intercurrent illness (one case) or failure to take the prescribed medication (2 cases)

There was a striking difference in the hematopoietic effect of the two forms of therapy When iron alone was taken the initial fall in hemoglobin was almost as pronounced as that following the earlier blood donation when no medication was taken In addition, during the first three or four days complaints of drowsiness, lassitude, and weakness were common Upper respiratory infections were occasionally reported even in the milder months of the year Recovery from the hemorrhagic anemia was gradual and generally completed in about twenty-six days, as compared with thirty days in the control study When iron-plus copper therapy preceded the blood donation the profound initial fall in hemoglobin was not observed The subsequent hemoglobin curve was an almost horizontal line and at no time did a significant anemia exist Especially after the iron and copper medication was the absence noted of the symptoms mentioned above, including the respiratory infections

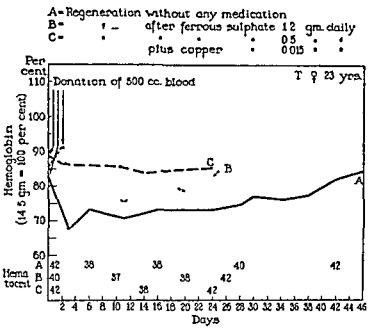

CHART 2 Typical example of blood regeneration in one of the subjects of the group illustrated in Chart 1

Discussion

The literature, both from experimental and clinical standpoints, on the relative merits of iron alone and iron plus copper as blood regenerating agents is extensive No purpose would be served by our attempting a discussion of the controversy at this time, and those interested are referred to the monographs by C A Elvehjem,[1] J H Hutchison,[2] and J H Latsky [3]

Briefly stated, it has been shown that traces of copper are ubiquitous in foods Hence, absolute copper starvation is difficult to obtain However, in most cases the ordinary means of supply appear to be inadequate to satisfy the increased demand caused by extensive blood loss

Copper functions as a catalyst for the conversion of storage iron into hemoglobin iron It is not needed for the assimilation and storage of iron During the recovery period from hemorrhagic anemia in which there is sudden demand for fresh hemoglobin copper is withdrawn from its stores and is mobilized in the circulating blood [1]

Our study shows that there is a striking difference in the hematopoietic effects of iron plus copper and iron without copper Whereas premedication prior to blood donation with iron plus copper was followed by only a slight drop in hemoglobin, premedication with iron alone was followed by a decided drop in hemoglobin which was almost as great as that observed when no medication was administered The observation indicates that copper probably plays an important role in hemoglobin synthesis, and that the amount of copper stored from the usual diet is

Chairman's Address, Section on Anesthesiology

PNEUMATOLOGY

F PAUL ANSBRO, M D , Brooklyn, New York

(From the Department of Anesthesiology of the Kings County Hospital and the Long Island College Hospital and the Long Island College of Medicine)

THE term "pneumatology" is derived from the Greek words *pneuma*—"air"—and *logos*—"treatise" The word was invented to fill the need for a descriptive term which would be adequate to cover the allied sciences of inhalation anesthesia, resuscitation by inhalational methods, and oxygen and helium therapy

Many years ago, Meltzer[1] interested the medical world in this concept and promulgated efforts to place the science upon an equitable footing with the other medical sciences His original work was followed by that of Flagg,[2] who has so notably contributed to popularizing the word and interesting others in it The need for the association of these allied sciences is evident First, because they are all based on inhalation of gases, second, because a basic knowledge of one branch is essential for the knowledge of the other, and third, they are mutually complementary to each other The pneumatologist, hence, is one skilled in the administration of inhalation anesthesia, the resuscitation of the asphyxiated patient from whatever cause, and the indications and methods of administering oxygen and helium therapy

Modern anesthesia by inhalation has become an integral part of the medical education of today In the majority of the medical colleges of this state, the teaching of anesthesiology is now on a well-established basis The medical student is, during his course, instructed in the fundamentals of the pharmacology and physiology of anesthesia and in the application thereof in the operating room No longer is inhalation anesthesia relegated to a minor course nor is it treated as the stepchild of the medical sciences Rather, in the last decade, it has taken a great forward step and is considered in most medical schools as a course of importance by the faculty It is accepted eagerly by the students as a valuable part of their armamentarium as physicians During the past ten years, many new methods and agents have been developed and brought to perfection Cyclopropane, developed just ten years ago by Waters and Schmidt,[3] has, over the course of hundreds of thousands of administrations, achieved a place of great importance Divinyl-ether, another new agent, has found its niche The carbon dioxide absorption method has reached its zenith of perfection and the uses of the older agents, such as ether and chloroform, have been developed so as to utilize their valuable properties in better ways than formerly

The pneumatologist of today has spent his time elsewhere than at the operating table He has contributed valuable research in the pharmacology and toxicology of anesthetic agents in the laboratory and has become increasingly interested in the care of the postoperative patient He has become well versed in bronchoscopy and in many instances is prepared to perform the so-called "postanesthetic toilet" upon the airway of the patient[4] These endeavors have borne fruit not only in preventing postanesthetic complications and decreasing their incidence but also in treating complications after they have arisen and has thereby been a valuable factor in decreasing postoperative morbidity and mortality, which should be an inestimable boon to surgery

Resuscitation

Of all the branches of the medical sciences, the physician seems to know the least about resuscitation As Henderson has said, "Unless one is burned alive, the tissues of one's body always die of asphyxia"[5] Yet, in the very circumstances in which the acute asphyxias occur, the physician finds himself unable to cope with the situation and of necessity is compelled to call in the aid of laymen who, incidentally, in the form of rescue groups, are doing valuable work The most common causative factors of respiratory depression and paralysis are drowning, carbon monoxide poisoning, smoke poisoning, poliomyelitis, electric shock, drugs, mechanical suffocation, anesthetic accidents, and asphyxia neonatorum All of these causative factors end in the common result—asphyxia

In order to treat them properly, the pneumatologist follows the three rules of treatment as laid down by Flagg[6] and developed by Ruth,[7] *viz*

1 *Insure the patency of the airway* —This may be occluded by a foreign body, fluid in the respiratory tree (as in drowning), tracheal collapse following thyroidectomy, débris in the newborn

Read at the Annual Meeting of the Medical Society of the State of New York New York City May 9 1944

inadequate to meet the emergency of blood regeneration following profound blood loss.

The data reveals immediate recovery after medication with iron plus copper. Following copper plus iron the hemoglobin values described an almost horizontal line, while after iron alone an average of twenty-six days was required for restoration to the initial level and, with no medication, thirty days.

It should be noted that when adequate copper is given the daily dosage of ferrous sulfate with copper was in the order of 0.5 Gm. per day, as compared with 1.2 Gm. per day when ferrous sulfate is administered without copper. This is of clinical significance because relatively high iron medication is followed frequently by undesirable gastrointestinal disturbances.

It should again be repeated that our subjects were in good health except for the state of acute hemorrhagic anemia which had been induced by voluntary blood donations, and our data are thus free from the possibility of unknown vitiating factors. During the experiment these individuals continued their normal existences and followed their usual diets.

The practical application of these findings under present conditions should be emphasized. It is recommended that agencies obtaining blood from donors administer copper-iron medication in a form similar to that described above to prevent hemorrhagic anemia and to accelerate the regeneration of hemoglobin.

Summary and Conclusions

Using blood donors, normal except for hemorrhagic anemia resulting from blood donation, it was found that premedication with an iron- and copper-containing medication prevented the usual precipitous depression of hemoglobin following blood donation. Premedication with ferrous sulfate did not prevent this marked depression; in fact, the depression was essentially the same as it was when the medication was withheld.

Following a donation of 500 cc. of blood and after copper-plus-iron medication the hemoglobin values described an almost horizontal line; after iron medication alone a definite anemia generally appeared which required an average of twenty-six days for recovery; when no medication was given the blood values were restored to the initial level after an average of thirty days.

Whereas the average diet contains an amount of copper adequate for the usual rate of hemoglobin synthesis, the copper stores appear to be inadequate for a greatly accelerated rate of hemoglobin synthesis.

Data are presented which support the claim that copper functions as a catalyst essential for the conversion of stored iron to hemoglobin.

Acknowledgment.—Part of the expenses incurred in this study were defrayed by the Lakeside Laboratories, Inc., Milwaukee, Wisconsin. The copper-iron preparation (Licuron-B) was supplied by the Lakeside Laboratories.

TRANSLATION OF MEDICAL BOOKS FOR LATIN AMERICAN USE

Important books of this country, particularly in the fields of science, medicine, and technology, will be made more readily available in Spanish and Portuguese translations for peoples of the other American republics as the result of a project to be conducted by Science Service, the nonprofit scientific institution, as a part of the Department of State's broad program for intellectual cooperation in the Western Hemisphere. Spanish and Portuguese translations of American books, issued by publishers in the other American republics as well as by United States publishers, will receive financial aid under this project. Books originally published in Spanish and Portuguese will be made available in English in the United States under provisions for similar aid to United States publishers. A grant-in-aid by the Department of State provides Science Service with funds to help defray the costs of translations, to obtain and distribute copies of the translated books to libraries, institutions, and other organizations and to cooperate otherwise in making the literature of any one American republic available to other peoples on the two continents. The purpose of this two-way translation program is "to overcome the barriers raised by difference of language by making available to the peoples of the other American republics the writings which represent the thought and the cultural and intellectual life of the United States, and making available to the people of the United States the writings which represent the thought and cultural and intellectual life of the peoples of the other American republics." Suggestions as to translations needed are being received from officials, scientists, educators, publishers, and others in this country and the other American republics. This program should contribute materially to the increasing interdependence and good will of physicians and scientists in our own country and in our sister republics.—*Editorial, J.A.M.A., Oct. 14, 1944*

Chairman's Address, Section on Anesthesiology

PNEUMATOLOGY

F. Paul Ansbro, M.D., Brooklyn, New York

(From the Department of Anesthesiology of the Kings County Hospital and the Long Island College Hospital and the Long Island College of Medicine)

THE term "pneumatology" is derived from the Greek words *pneuma*—"air"—and *logos*—"treatise." The word was invented to fill the need for a descriptive term which would be adequate to cover the allied sciences of inhalation anesthesia, resuscitation by inhalational methods, and oxygen and helium therapy.

Many years ago, Meltzer[1] interested the medical world in this concept and promulgated efforts to place the science upon an equitable footing with the other medical sciences. His original work was followed by that of Flagg,[2] who has so notably contributed to popularizing the word and interesting others in it. The need for the association of these allied sciences is evident. First, because they are all based on inhalation of gases; second, because a basic knowledge of one branch is essential for the knowledge of the other; and third, they are mutually complementary to each other. The pneumatologist, hence, is one skilled in the administration of inhalation anesthesia, the resuscitation of the asphyxiated patient from whatever cause, and the indications and methods of administering oxygen and helium therapy.

Modern anesthesia by inhalation has become an integral part of the medical education of today. In the majority of the medical colleges of this state, the teaching of anesthesiology is now on a well-established basis. The medical student is, during his course, instructed in the fundamentals of the pharmacology and physiology of anesthesia and in the application thereof in the operating room. No longer is inhalation anesthesia relegated to a minor course nor is it treated as the stepchild of the medical sciences. Rather, in the last decade, it has taken a great forward step and is considered in most medical schools as a course of importance by the faculty. It is accepted eagerly by the students as a valuable part of their armamentarium as physicians. During the past ten years, many new methods and agents have been developed and brought to perfection. Cyclopropane, developed just ten years ago by Waters and Schmidt,[3] has, over the course of hundreds of thousands of administrations, achieved a place of great importance. Divinyl-ether, another new agent, has found its niche. The carbon dioxide absorption method has reached its zenith of perfection and the uses of the older agents, such as ether and chloroform, have been developed so as to utilize their valuable properties in better ways than formerly.

The pneumatologist of today has spent his time elsewhere than at the operating table. He has contributed valuable research in the pharmacology and toxicology of anesthetic agents in the laboratory and has become increasingly interested in the care of the postoperative patient. He has become well versed in bronchoscopy and in many instances is prepared to perform the so-called "postanesthetic toilet" upon the airway of the patient.[4] These endeavors have borne fruit not only in preventing postanesthetic complications and decreasing their incidence but also in treating complications after they have arisen and has thereby been a valuable factor in decreasing postoperative morbidity and mortality, which should be an inestimable boon to surgery.

Resuscitation

Of all the branches of the medical sciences, the physician seems to know the least about resuscitation. As Henderson has said, "Unless one is burned alive, the tissues of one's body always die of asphyxia."[5] Yet, in the very circumstances in which the acute asphyxias occur, the physician finds himself unable to cope with the situation and of necessity is compelled to call in the aid of laymen who, incidentally, in the form of rescue groups, are doing valuable work. The most common causative factors of respiratory depression and paralysis are drowning, carbon monoxide poisoning, smoke poisoning, poliomyelitis, electric shock, drugs, mechanical suffocation, anesthetic accidents, and asphyxia neonatorum. All of these causative factors end in the common result—asphyxia.

In order to treat them properly, the pneumatologist follows the three rules of treatment as laid down by Flagg[6] and developed by Ruth,[7] *viz.*:

1. Insure the patency of the airway.—This may be occluded by a foreign body, fluid in the respiratory tree (as in drowning), tracheal collapse following thyroidectomy, debris in the new born,

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 9, 1944.

2. Supply oxygen to the lungs rapidly.— There are four methods of doing this:

(*a*) Mouth-to-mouth breathing. This is a most useful method, inasmuch as no apparatus is required and the means of its accomplishment are always at hand. It is a valuable method and has saved many lives, particularly in infants. It is occasionally destructive, since the overenthusiastic resuscitator is liable to exert more intrapulmonic pressure than the lung can withstand. It is important to remember that a safe intrapulmonic pressure in infants is 10–15 mm. of mercury and in adults, 40–50 mm. of mercury. Wilson[8] has stated, "The lung tissue cannot, itself, be adequately aerated (inflated) even by pressures high enough to be injurious or destructive." Henderson[9] answered, "Intratracheal insufflation is not done for the purpose of inflating the lungs. It should not inflate, and if properly done it cannot inflate. It merely supplies oxygen so deep in the respiratory tract that the blood is oxygenated without any respiratory movement of the chest." In applying mouth-to-mouth resuscitation, therefore, only a moderate pressure should be exerted, as harmful effects may ensue otherwise.

(*b*) Manual methods. The Schaeffer prone-pressure method is accepted today as the most easily applied and most efficient of the various manual methods. In recent years there has been a great impetus given to the teaching of this method to various groups, particularly first-aid classes, and many lay people have become skilled in its use. It is an essential part of the physician's armamentarium that he be skilled, too, in its application. Other methods, *viz.*, Silvester arm-abducting method, Neilson prone pressure, Eve rocking, and Thomson lifting methods have found much favor among certain groups, particularly the Eve rocking method, which is very popular in the British armed services.

(*c*) Mechanical methods. There are many and varied types of mechanical resuscitators in the field, the very number of which indicates that no one type is entirely satisfactory. Any mechanical resuscitator should fulfill the three requirements as stated:

1. Insure the patency of the airway,
2. Supply oxygen to the lungs rapidly, and
3. Do this under measured pressure.

The only mechanical resuscitator that fulfills these three requirements is one that follows the principle of Meltzer and Flagg in the use of a laryngoscope and the employment of aspiration and intubation of the larynx and trachea as its primary *modus operandi*. Any other mechanical aid that neglects the first principle (insure the patency of the airway) is not worthy of classification as a resuscitator; these are merely inhalators. A large percentage of asphyxias are caused by obstructions in the upper respiratory tract, hence a mere inhalator which supplies oxygen only to the mouth and not deep in the respiratory tree is useless as such, hence, pneumatologists are skilled in visualizing the larynx and introducing tubes into the trachea after aspiration of the passage. The frequent use of "suck-and-blow" apparatus has been instrumental in popularizing this type of machine[10] but it is useless when the cause of the asphyxia is obstruction of the airway. More recent experimental work has demonstrated that "suck-and-blow" is, in itself, effective when the airway is patent, even using inert (asphyxiating) gases.[11] The pneumatologist must determine the method of resuscitation and the type of resuscitator to be used (if at all) on each case and to remember that Henderson has said, "Prolonged, forcible, 'suck-and-blow' artificial respiration may cause injury to the lungs, shock, and death."[12] If the asphyxia is not caused by mechanical obstruction, then the various "suck-and-blow" resuscitators may prove useful. This can be accomplished without the use of high-priced instruments by merely employing the rubber bag of the anesthetic machine and rhythmically compressing it with the hand. Hand pressure, however, should be so performed as to avoid pressures that are excessive. Mechanical "suck-and-blow" resuscitators may perform this function and without danger of overdistention of the alveoli if they are based upon the action of pistons which are so calibrated as not to exceed 40–50 mm. of mercury intrapulmonic pressure for the adult, and 10–15 mm. for the infant. In the latter class may be placed the E and J resuscitator and the Emerson resuscitator. The Kreiselman resuscitator has also found favor. The Drinker resuscitator (the so-called iron lung) is a very valuable machine for use in chronic or long-standing asphyxias, such as in poliomyelitis or Landray's paralysis. It should be available in every community.

(*d*) Drug treatment. The analeptics usually employed are metrazol, coramine, alphalobeline, and lobeline hydrochloride. They occasionally prove valuable when used in conjunction with mechanical or manual methods. They are useless in asphyxia if used alone. Picrotoxin is of use in the treatment of barbiturate poisoning. It should be borne in mind in using these drugs that they are convulsants and if used improperly, or to excess, may result in a convulsive state and consequent irreparable damage to the physical status of the patient.

(*e*) Supportive measures. The pneumatologist employs heat as one of his most effective aids in resuscitation. The heat can be applied in the

form of hot-water bottles or warm blankets or a warm atmosphere It should be particularly remembered that the retention of body heat is essential in effecting resuscitation and the cold tubbing employed in attempting infant resuscitation should be abandoned. The Trendelenburg position should be employed when indicated, infusions of glucose or saline utilized, and, occasionally, cardiac stimulation by either the introduction of a needle into an auricle in an attempt to induce an auricular fibrillation which, in turn, may send stimuli through the bundle of His to the ventricles and cause them to contract, or if accessible, the arrested heart should be manually stimulated and artificial circulation thereby instituted. Modern thought on the subject of the needle into the heart is that the introduction of the needle sets up "action currents of injury" which cause the heart to contract It is felt that this is the stimulus and not the epinephrine which usually is injected through it

In asphyxia neonatorum, Flagg[6] gives the procedure, *viz*, "make the diagnosis of the degree of asphyxia present Into what class of asphyxia does this baby fall? (1) Is it really depressed? (2) Is it dying? or (3) Is it a borderline case?" Laryngoscopy is performed on the asphyxiated baby (the depressed baby does not need it) and aspiration of the airway follows If there is no reflex of the glottis (due to anoxia) put in a tracheal tube and insufflate carbogen at a pressure of 10–15 mm of mercury. This procedure is made possible only by a resuscitator that employs a laryngoscope, intubating tube, and measured pressure and has been the means of preventing many newborn

> For darker closets of the tomb "[13]

Oxygen and Helium Therapy

The pneumatologist has, in this category, a knowledge of treatment that all too often has been given over to the layman The various commercial companies supplying oxygen and helium therapy have performed their function so well that physicians have been wont to place the treatment of their asphyxiated patients needing oxygen and helium into the hands of laymen employed by these companies The various medical sciences have conveniently forgotten that the treatment of the asphyxiated patient with oxygen is a medical subject and not one for lay minds In ordering oxygen therapy for the patient, the physician should literally write his prescription for oxygen just as he would write any other prescription for the treatment of the patient Too often we hear oxygen ordered without any record of the dosage required Various conditions, like varying degrees of asphyxia, require varying concentrations of oxygen as well as varying lengths of time in its application

The use of oxygen in painful conditions of the myocardium[14] and in chronic pulmonary conditions is of established value[15] as well as its positive indication in the treatment of pneumonia.[16] Helium and oxygen mixtures have been found of critical value in the treatment of asthma and obstructions of the larynx and trachea.[17] Its efficient action in relieving postoperative gaseous distention can be personally affirmed by the writer Severe migraine headaches have often vanished under its influence.[18] The pneumatologist has become familiar with the indications for oxygen and helium therapy, the apparatus used in its administration, and the concentrations necessary for the adequate treatment of the conditions in which it has been found useful He is skilled in the requirements of oxygen therapy in regard to the oxygen supply, oxygen regulators, and the proper administering apparatus as well as the principles of effective therapy as regards frequent analyses of oxygen concentration and the control of cost Without these principles, the use of oxygen on the asphyxiated patient and of helium-oxygen mixtures becomes not only ineffective and expensive but also, in many cases, a therapeutic travesty

Summary

The pneumatologist is a doctor of medicine adequately trained and highly skilled in the administration of inhalation anesthesia He is experienced in the methods of and indications for resuscitation of the asphyxiated patient He has a comprehensive knowledge of the physiology of the body as regards oxygen metabolism and the utilization of the various methods employed in combating anoxemia and anoxia He literally stands at the crossroads of the medical sciences, an augury of good to the surgeon and internist, and

Discussion

Dr. Paluel J. Flagg, *New York City*—If one wishes to set a date for the more recent beginnings of pneumatology, which, as might be expected, has extended down the ages, he will doubtless find that inhalation therapy has led the way. Among the pneumatologists, Priestley, Lavoisier, Hickman, and Beddoes, Sir Thomas Beddoes made a formal beginning in the establishment of his Pneumatic Institute at Clifton near Bristol, England, in the year 1789. Half a century later Jackson, Wells, and Morton initiated the use of the gases nitrous oxygen and ether for the control of pain. Oliver Wendell Holmes, by calling this activity anesthesia, confined the pneumatologist to the operating room and delayed for more than half a century the third phase of this specialty, resuscitation, so ably evolved by Haldane, O'Dwyer, Meltzer, and Henderson. These men drew attention in no uncertain manner to the extramural needs for the competent pneumatologist.

The foregoing references serve to clarify the basic distinction between a restricted field of medicine and the physician who becomes active in such a field. Anesthesia is necessarily restricted by its terminology. It cannot be expanded at will. For example, it is not possible to regard the treatment of terminal poliomyelitis, electric shock, submersion, problems of high-altitude flying, chemical warfare, or carbon monoxide poisoning, as anesthesia. And yet you know and I know that where the work of other physicians ceases, when unconsciousness supervenes, ours begins. We are perfectly at home with the phenomena of unconsciousness. We, as physicians, are not only at home with the pathologic physiology incidental to this state, but we know how to induce, direct, and safeguard unconsciousness. No other group of physicians can make this claim.

As a physician I stand here today to express my debt to the field of anesthesia for the opportunity which it gives me to maintain an intimate acquaintance with the unconscious patient. My most important concern is to avoid mortality and to reduce morbidity. Sometimes this must be done at the expense of pleasing the patient. Anesthesia is my home. I do not propose to abandon it. On the other hand, the able physician does not confine his work to office practice. He responds to the call for help from those whom he is specially qualified to treat or direct.

If it be granted that general anesthesia in the average hospital is impractical without the use of nitrous oxide, oxygen, ether, cyclopropane, ethylene, carbon dioxide, and helium, and that this therapeutic use of gases, or pneumatology, includes resuscitation and inhalation therapy, it follows that this terminology must also include rectal and intravenous therapy, for that which contains the whole must contain its parts.

The pneumatologist applying pneumatotherapy in cooperation with the pneumatologic technician in anesthesia, resuscitation, and inhalation therapy provides a specialty calling for the best that medicine has to give, a specialty paralleling in scope and importance the great fields of internal medicine and surgery.

"DOCTOR JONES" SAYS—

"Alcoholics Anonymous"—ever hear of 'em? Well, sir, there's an organization that's grown up in the last few years that's doing a real, practical job. A man that's well known in the public health line—a letter he wrote awhile ago—he called it one of the most outstanding examples of practical Christian service he'd ever known. Four years ago (the last figures I happen to have) they had around 500 members, with chapters—units or whatever they call 'em—scattered over the country. They're saving 'emselves, these fellows—and some of 'em are big shots, holding important positions—but they're getting their strength to do it mainly from helping others.

A series of stories about this organization and its work (I've got a reprint of 'em here)—these articles appeared first in a paper in Houston, Texas. They were written by a newspaper man that'd been practically a down-and-out alcoholic. Not only that but he had some lung trouble and two institutions had refused to take him in: thought he was beyond help. Then, some way, he got connected up with "Alcoholics Anonymous." He'd been on the water-wagon ever since and was holding a good job on this newspaper. Like the rest of 'em, he was out to help others that were in the same pickle he'd been in. Only "alcoholics" are eligible for membership. That don't mean just drinking—not their definition. A lot of people use alcoholic beverages more or less regularly and some of 'em, once in a while when they get out with the boys, they get lit up a little. But if they can control it—stop if they want to—look at a drink and pass it up, it may be bad for 'em but they aren't alcoholics. A confirmed alcoholic, when the urge hits him, taking a drink and then more of 'em—it's just as automatic as dodging if you see something falling on you. If it wrecks his career he can't help it—not until he's "born again," however that may come about.

Being an alcoholic isn't the only qualification for membership. They've got to have a real desire to quit and recognize that they can't handle it alone. And they've got to believe there's some power stronger than their own that can help 'em: call it God or whatever they want to. Naturally they don't all come through but they're helping a lot where doctors and the rest of 'em have failed. Their batting average is good enough so I'd advise any "qualified" person to look 'em up.—*Paul B. Brooks, M.D., in Health News, July 31, 1944*

Diagnosis

CLINICOPATHOLOGIC CONFERENCES

Fourth Medical Division of Bellevue Hospital

Date: December 21, 1944

Conducted by: Dr. Harry A. Solomon

Dr. Marilyn T. Schittone: H. K., a 64-year-old German housewife, was admitted to the medical service on February 12, 1944, with chief complaints of weakness, dyspnea, and orthopnea of several weeks' duration. She had had known marked hypertension for at least seven years, with systolic readings as high as 240. The past history revealed that a radical mastectomy had been performed in 1941 for adenocarcinoma of the left breast. Her menopause at 45 had been uneventful. The patient had otherwise been well until about six weeks before admission, when she had a rapid development of dyspnea which progressed to the rest type, three-pillow orthopnea, anorexia, weakness, undue fatigue, and a moderately productive nonbloody-tinged cough. There was no known weight loss. She complained of frequent consciousness of heartbeat, but apparently did not have palpitations, pain, or edema. On the day before admission, she vomited all food and fluids taken.

Examination on admission revealed a middle-aged white woman who appeared to be ten years younger than her stated age. She rested comfortably in bed, and did not appear to be acutely ill. The skin and mucous membranes were moderately pale.

The temperature was 100.2 F., pulse 92, respiration 22, blood pressure 218/110. Head, ears, nose, and throat were negative. The fundi showed moderate narrowing of the arteries. There were no hemorrhages or exudates. The trachea was deviated to the right. The thyroid was not palpable. There was a large, healed radical mastectomy scar on the left side of the chest. The right breast was normal. There was no palpable lymphadenopathy. The lungs were clear to percussion and auscultation. The point of maximum intensity of the heartsound was in the fifth intercostal space in the anterior axillary line. There was a soft, precordial systolic blow. There were no thrills. The sounds were of fair quality. The rhythm was that of fibrillation with a rapid ventricular rate. Examination of the abdomen, rectum, and extremities was negative.

Laboratory Data: The white blood count on admission was 15,000 with a normal differential. The red blood count was 5,300,000; hemoglobin was 14.6 Gm. The urine showed 2 plus albumin and numerous white blood cells. Nonprotein nitrogen was 29. Serology was negative. On February 28 the urine showed 3 plus albumin and a moderate number of white blood cell clumps. The patient concentrated urine to 1.013 and diluted to 1.001. On March 6 the nonprotein nitrogen rose to 39. The creatinine remained normal. The white blood count fell to 12,800 on February 23 and to 10,000 on March 1, again with a normal differential. Electrocardiograms showed left axis deviation, auricular fibrillation, and occasional ventricular premature contractions. An x-ray of the chest showed sharp deviation of the trachea to the right and slight cardiac enlargement There was no evidence of metastatic deposits in the bony thorax or lungs.

Course: The patient ran a low-grade fever for two weeks. Careful examination failed to reveal a source of infection, and urine cultures were negative. The patient became afebrile in the third week and remained so. On February 25, medium moist rales were heard in both bases and the fundi showed multiple hemorrhagic areas on the right. Blood pressure at this time was 225/140. Digitalization was begun on February 29, the lungs cleared, and the heart rate slowed down to 88. The patient was discharged as improved on the twenty-sixth hospital day.

Second Admission: The patient was readmitted on June 7, 1944, with the same complaints and a history of dependent edema on several occasions after her discharge and on admission.

Examination at this time revealed a dyspneic, orthopneic woman who now appeared to be her stated age. There were medium moist rales at both bases. Percussion was normal. The heart rate was rapid and grossly irregular, with a pulse deficit of 30. Blood pressure was 190/120. The liver was three fingerbreadths below the costal margin and not tender, and there was marked dependent edema.

Laboratory Data: The white blood count on admission was 16,450, with 76 per cent polymorphonuclear cells. The red blood count was 4,180,000; hemoglobin was 13 Gm. The urine showed 3 plus albumin and many white blood cells and granular casts. The specific gravity reported at this time was 1.022. Urine examina-

tion on June 12 showed no albumin and few white blood cells with occasional hyaline casts. Nonprotein nitrogen was 52.

Course: Evidence of fluid at the right base necessitated a chest tap which was done on the thirteenth hospital day and yielded 350 cc. of clear fluid with a specific gravity of 1.015 and 180 lymphocytes.[3] On the day following tap a low-grade febrile curve which had persisted for four days before that returned to normal. On June 27 she began to vomit, complained of diffuse right upper quadrant pain, and had a temperature of 102 F. Two days later she complained of marked pain in the left lower quadrant as well. Palpation was negative but difficult because of the marked voluntary spasm of the abdominal wall. The symptoms subsided with sedation and antispasmodics. On July 27 one observer suggested that the basal metabolic rate be determined because the patient showed an enlarged left thyroid lobe which was mostly substernal, a left supraclavicular soft nodule which was thought to be aberrant thyroid tissue, auricular fibrillation, weight loss, diarrhea, heat intolerance, and stare. The basal metabolic rate was +12, cholesterol 148, esters 67. An x-ray revealed substernal enlargement of the thyroid with deviation of the trachea to the right. Electrocardiograms were as on the previous admission. The patient was given a trial with Lugol's solution for one month. Signs of progressive cardiac failure continued in spite of digitalization. The cholesterols increased to 286 with esters of 143, but the basal metabolic rate increased to +15. On the eighty-fourth hospital day the patient insisted upon discharge, saying she felt much better, and she was referred to the Thyroid and Cardiac clinics for further care.

Third Admission: The patient was readmitted on September 21, 1944, with the same complaints as before. In the period since the first admission she had lost about 40 pounds. Examination on admission revealed a markedly dyspneic, emaciated, apprehensive woman. The left base was flat to percussion with diminished-to-absent breath sounds and tactile fremitus. The heart was as before. The liver was two fingerbreadths below the costal margin. There was 1 plus edema of the ankles. The hands showed a fine tremor.

Laboratory Data: The white blood count on admission was 12,600. The urine showed 2 plus albumin and a specific gravity of 1.030, cholesterols 114, esters 87, nonprotein nitrogen 60, creatinine 1.67. An x-ray of the chest showed pleural effusion on the left.

Course: On the second hospital day the patient became disoriented. The nonprotein nitrogen had fallen to 47, with a carbon-dioxide combining power of 16 volumes per cent. A chest tap was done on the fifth day and yielded 850 cc. of fluid. On the thirteenth day another chest tap yielded 750 cc. of semitranslucent fluid which was amber in color and contained 350 white blood cells with 97 per cent lymphocytes; its specific gravity was 1.010. By this time the patient had become comatose, was anuric, and showed Kussmaul respiration. The nonprotein nitrogen was 100; the carbon-dioxide combining power was 20 volumes per cent. Creatinine was 2.5. The patient died on the fifteenth hospital day.

Discussion

DR. HARRY A. SOLOMON: This patient was known to have had persistently high blood pressure for over seven years, but, except for a breast amputation for adenocarcinoma several years ago, was asymptomatic until six weeks before admission when she developed progressive dyspnea, orthopnea, cough and profuse expectoration, and profound weakness. With the hypertensive background and the findings of an enlarged heart which was fibrillating rapidly, visceral congestion, particularly pulmonary and renal, high diastolic and systolic pressure, and eye-ground changes of advanced arteriolar disease, it was evident that she was presenting the clinical features of decompensated hypertensive heart disease. It was not easy to explain the rapid and extensive cardiac damage which was too intractable to therapy to be attributed to some minor cause reducing cardiac reserve, such as a disturbance of rhythm, transient toxic state, overload, etc. On the other hand, there was nothing in the history or electrocardiogram to indicate that the severe myocardial insufficiency was provoked by a coronary insult, and while it appeared likely that the condition was simply one of physiologic exhaustion of a hypertensive heart, the x-ray of the chest did not show the marked cardiac dilatation and extreme pulmonary congestion usually seen at this time. Likewise, no cause was found for the persistent fever and leukocytosis other than visceral congestion of heart failure, unless one inferred that silent myocardial or pulmonary infarctions were present.

On the second admission the congestive heart failure was more advanced, with liver enlargement and dependent edema, but general deterioration was very striking. Other changes noted were weight loss with evident emaciation, eye stare, tremors of hands, diarrhea, heat tolerance, and rapid auricular fibrillation. Mental alertness was strikingly acute in contrast to the extreme physical exhaustion. Therefore hyperthyroidism was suspected and the upper lobe of a

substernal goiter was felt behind the clavicle on the left when the patient was asked to cough, and the chest plate showed that the trachea was displaced to the right. The metabolism was taken and reported to be +15. With a diagnosis of hyperthyroidism it was now possible to explain the prolonged resistant fever and the refractiveness of the rapid auricular fibrillation to digitalis. Although a basal metabolism determination after iodine medication was reported unchanged, the effects of iodine in controlling the hyperpyrexia, raising the serum cholesterol, and improving the general condition of the patient were characteristic. Thiouracil was used later and this produced a further beneficial result, even a notable decrease in the size of the substernal goiter as noted on x-ray.

In the left supraclavicular region an irregular mass about 2 inches in diameter was noted. This was thought to be aberrant thyroid tissue or metastatic from retrograde extension of the malignancy. This mass was soft, however, and no other metastatic lesions were found.

On the third and final admission, the patient was *in extremis*. Pulmonary congestion was more extensive and bilateral pleural effusions recurred despite tappings, especially on the left side. Because of the highly cellular content of the pleural fluid, almost entirely lymphocytes, the possibility of tuberculous pleuritis was considered with possible relationship to matted cervical lymph nodes.

Uremic symptoms with acidosis, oliguria, azotemia, etc., appeared rapidly, but whether this renal failure was secondary to heart failure or the result of an advanced contracted nephropathy was speculative. From my clinical evaluation, I felt that the following might be expected:

1. Hypertensive disease with dilated heart, visceral congestion of longstanding heart failure, and arteriolar sclerosis.
2. Substernal goiter modified by iodine and thiouracil medication.
3. Left pleural effusion—reaction or tuberculous.

Dr. Appelbaum, what is your impression of this case?

DR. EMANUEL APPELBAUM: This is a rather complicated case. I stated that my impression was of hypertensive and arteriosclerotic heart disease with masked hyperthyroidism. The azotemia was extrarenal, caused by circulatory failure. I did not concentrate on the pleural effusion. The terminal episode is puzzling. The specific gravity was very high, and the urine does not appear to have been typical of renal failure. The facts are sufficient to warrant the diagnosis of hypertensive cardiovascular disease. But the diagnosis of hyperthyroidism is open to question. There was no response to Lugol's solution, and no significant elevation of the initial basal metabolic rate. The pleural effusion may have been on a tuberculous basis.

DR. SOLOMON: Hypertensive hearts in failure are usually dilated. This one was not. The gland in the neck was either not enlarged or not noticed on the first admission.

DR. APPELBAUM: How do you explain this patient's high specific gravity?

DR. SOLOMON: She was almost anuric. The specific gravity was high because of the small output.

DR. APPELBAUM: That makes no difference, one still can't concentrate in renal failure.

DR. SOLOMON: Dr. Nammack, what is your impression?

DR. CHARLES H. NAMMACK: I agree with you, but I do not agree about the thyrotoxicosis. I feel that the chest fluid was probably a transudate in a tapped chest and part of the patient's myocardial insufficiency. What is your case for hyperthyroidism?

DR. SOLOMON: Rapid deterioration, diarrhea, heat tolerance, auricular fibrillation, substernal mass, fine hand tremors, and stare all point to hyperthyroidism.

DR. HENRY C. FLEMING: What do you think caused the right upper quadrant pain?

DR. SOLOMON: I don't know. It may have been referred from the chest.

DR. BEECKMAM J. DELATOUR: It is my impression that this patient suffered a myocardial infarction. That would explain the right upper quadrant pain, fever, leukocytosis, and vomiting.

DR. SOLOMON: There was nothing in the electrocardiogram to suggest that the patient had one.

DR. DELATOUR: Was one done after the pain?

DR. SOLOMON: Yes; there were no changes.

DR. DELATOUR: The patient was fibrillating and that would obliterate changes.

DR. FLEMING: With right upper quadrant pain one might think of infarction of the hepatic artery or one of its branches.

DR. ARNOLD KOFFLER: I think masked hyperthyroidism is a good possibility.

DR. KATHERINE KELLEY: I think this patient had carcinomatous metastases to the pleura, explaining the effusion.

DR. ZACHARY SAGAL: Very little importance has been attached to the tracheal deviation in this discussion. I think that metastatic mediastinal malignancy was responsible.

DR. MAX TRUBEK: The sudden dyspnea is easily explained by metastatic malignancy. The

azotemia was extrarenal, the specific gravity was high, creatinine low. There was no hyperthyroidism. If anything, there was a colloid goiter.

Presentation of Pathology

DR. HENRY SPITZ:

Anatomic Diagnosis:

Generalized arteriosclerosis
Arterio- and arteriolosclerosis of kidneys
Arteriolosclerosis of pancreas, adrenals, gastrointestinal tract, spleen, liver, and gallbladder.
Hypertrophy and dilatation of heart
Sclerosis of coronary arteries, severe
Infarcts of myocardium
a. Old infarct of left ventricle with aneurysmal dilatation
b. Recent infarcts of both auricular appendages
Mural thrombi of left ventricle and both auricular appendages
Hydrothorax, bilateral
Thrombosis of pulmonary artery
Infarct of lung
Diverticulosis of descending and sigmoid colon with diverticulitis, perforation, and pelvic abscess formation
Secondary carcinoma of anterior chest wall, diaphragm, and mediastinal lymph nodes following carcinoma of breast previously removed by radical mastectomy
Chronic cholecystitis
Cholelithiasis
Adenoma of thyroid, "fetal" type, with hemorrhage and cystic degeneration
Lobular pneumonia

This case is remarkable because of the multiplicity of lesions, some of which were unsuspected but formed the basis and explained the mechanism of several symptoms which were subject of extensive clinical speculation. This patient apparently had arterio- and arteriolosclerosis of long standing with hypertension and old and recent infarcts of the myocardium in the presence of severe sclerosis of the coronary arteries without evidence of old or recent occlusion of the main branches. This type of lesion has been repeatedly described as occurring in hypertrophic hearts due to coronary insufficiency, and this mechanism seems to apply to our case. Infarcts of the auricles, though less common, have also been reported in various instances. These lesions of the heart amply explain the clinical symptoms and the postmortem findings indicating heart failure. The important lesion, however, which escaped clinical recognition, was the diverticulitis with perforation and abscess formation, which apparently caused the episode of severe abdominal pain associated with rise in temperature and leukocytosis. The lesion apparently is also responsible for increasing wasting and hypermetabolism which has been interpreted as evidence of hyperthyroidism. No retrosternal struma was found, nor was there any evidence of hyperplasia, either in the "fetal" adenoma or in the remainder of the thyroid gland. The metastases following the carcinoma of the breast were only of minor extent but locally invasive, involving skin, fascia, intercostal muscles, and nerves. It is questionable whether they represent a major factor in the evolution of the case. Lobular pneumonia apparently was a terminal event.

MUSICAL THERAPY IN MENTAL HOSPITALS

The National Music Council has conducted a survey to ascertain to what extent music is at present used in leading nervous and mental hospitals throughout the country, and what the results have been. Two hundred and nine hospitals answered a questionnaire, and these have a bed capacity which ranges from 33 to over 8,000. Only one hundred and ninety-two of the two hundred and nine used music. The rest were frustrated by war restrictions and economies, shortage of personnel, and lack of facilities. There are performances in one hundred and sixty hospitals by visiting artists, gifted patients, church choirs, bands, and glee clubs. Recorded music is played by one hundred and fifty-two institutions.

That patients like music, there can be no doubt. But is it a healing aid? Only twenty-three hospitals reported that they used music for therapeutic reasons and one hundred and thirty-four used it for both recreation and therapy. Most directors of hospitals find that "recreation is therapy." Active participation in the making of music is generally considered more effective than mere listening. Group performance develops a spirit of cooperation and fellowship and helps patients to overcome their inhibitions.

The psychiatric staff of one hospital finds that the blare and dissonance of jazz "is a disturbing influence to all types of patients." Band music, spirituals, American folk songs are soothing. But music is not a specific for mental disorders. There is even the danger that the wrong music may be used by patients to express and reinforce delusional ideas.—*New York Times, Oct. 22, 1944*

SPONTANEOUS HYPOGLYCEMIA DUE TO ISLET-CELL TUMORS OF THE PANCREAS

Report of Two Cases and Review of the Literature

ROBERT M CLYNE, M D , HORACE M LEEDS, M D , and JOHN S COWDERY, M D ,
New York City

(From the Medical Service of the Lincoln Hospital)

IT IS our purpose to present two cases of tumor of the islet cells of the pancreas, one an adenoma, the other a carcinoma There is also presented a comprehensive review of the literature on this subject of the last four years

History

With the discovery of insulin in 1921 by Banting and his coworkers a new symptom complex arose The medical profession became aware of insulin shock and the symptoms of hypoglycemia In 1924 Seale Harris[1] published three cases with symptoms he believed to be caused by spontaneous hypoglycemia due to hyperinsulinism The first operative report was by Wilder *et al*[2] in 1927 This case proved to be an inoperable islet-cell carcinoma with hepatic metastasis Two years later Graham reported the first surgical cure of a patient with an islet-cell adenoma Since that time many additional case reports of islet-cell tumors have appeared in the literature

Frantz[3] in 1940 reviewed the literature of islet-cell tumors and was able to collect 96 cases 70 were benign islet-cell adenomata, 21 were suspected islet-cell malignancies, and 5 were definite malignancies with metastasis Hanno and Banks[4] in 1943 reviewed the literature on islet-cell carcinomata and were able to collect 21 proved cases, to which they added one more case Investigation of the literature since March, 1943, reveals four additional cases of islet-cell carcinoma[5-8] To these four we wish to add a case which was first seen and diagnosed on our medical service and was subsequently reported by Ballinger[9] in 1941 as an islet-cell carcinoma arising from aberrant islet-cell tissue in the liver To the 70 cases of adenomata reported by Frantz[3] we wish to add 56 cases* culled from the world literature from September, 1939, to January 1, 1944, plus one case of proved islet-cell adenoma of our own

Including 22 suspected malignancies reviewed by Whipple[10 11] in 1941, this makes a grand total of 176 islet tumors Of the 176, 127 were benign adenomata, 27 carcinomata, and 22 suspected carcinomata

Causes of Hypoglycemia

Hyperinsulinism —(1) administration of excessive amounts of insulin, (2) tumors of islets of Langerhans, benign and malignant

Spontaneous Hypoglycemia —(1) nervous or functional, (2) hepatic origin, (3) Simmond's cachexia, (4) Addison's disease and adrenal tumors, (5) cerebral degeneration, (6) pernicious anemia, (7) Fröhlich's syndrome, (8) acromegaly, (9) progressive muscular atrophy, (10) status thymicolymphaticus, (11) hypothyroidism, (12) lactation, (13) renal glycosuria, (14) functional disturbances of the sympathetic nervous system, (15) organic diseases of the nervous system, (16) miliary tuberculosis, and (17) Posturradiation of the pancreas

In this report we are considering cases of hypoglycemia due to tumors of the islet cells The rarity of this condition was brought out by Thomas[12] He estimated that adenomata are found in 1 to 800 to 1,000 autopsies Winters *et al*[13] were unable to find a single adenoma after a review of 13,000 autopsy records at Cook County Hospital Kerwin[22] reports that 11 islet-cell tumors have been encountered among 6,700 autopsies at the University of Toronto These figures are misleading, however, since in many instances the adenomata are microscopic in size and are missed by gross sectioning of the pancreas Subtotal pancreatectomy has been done in many instances with relief of symptoms, yet no adenoma was found

The youngest patient was 7 years of age, reported by Sauerbruch,[25] and the oldest was 60 years of age, reported by Vayo[27] In one half of the cases the patients were between 30 and 50 years old However, when one separates the cases with hypoglycemic symptoms from those in which such symptoms were lacking, it is found that the lower age groups are filled almost exclusively by patients who suffered from symptoms of hypoglycemia Greenlee, Lloyd, Bruechen, and McElroy[11] are of the opinion that there is no known procedure to definitely prove that a given case of hypoglycemia is due to a tumor of the islet cells of Langerhans They remark that Whipple has established the following triad of findings in hypoglycemia as warranting surgical exploration (1) definite repeated seizures of a vasomotor or a psychic disturbance coming on during the fasting period, (2) a blood sugar reading below 50 mg per 100 cc , and (3) immediate recovery from the seizure with the intake of sugar

Two tests have been used to help establish the diagnosis (1) the insulin tolerance test and (2) response to epinephrine In performing the insulin tolerance test five units of insulin are given intravenously after twelve hours of fasting After two hours there is no tendency for the blood sugar to reach normal levels if an adenoma of the islets is present Epinephrine is administered to rule out any disturbance in glycogen reserve If the blood sugar does not rise after its administration it would tend to indicate that the hypoglycemic state might

* These cases were found in the articles cited in References 7, 10–39

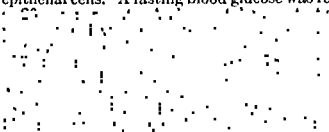
be due to lack of liver or tissue glycogen, rather than to a primary disturbance in the pancreas. In the case which they reported[11] hyperfunction existed in both an adenomatous goiter and in an adenoma of the islets of Langerhans. These two conditions were corrected by appropriate surgical therapy.

Meyer, Amtman, and Perlman[42] report a review of 71 cases of tumors of the islets of Langerhans in which the diagnosis was made preoperatively and confirmed at operation. Of the 71 patients 53 were completely relieved of symptoms postoperatively, 12 died at operation or shortly thereafter, and 1 was not relieved despite the removal of an adenoma. Rudd and Walton[19] present the opinion that in cases with a definite clinical and biochemical picture an adenoma is probably always present. Accessory pancreases are known to occur and a recognition of their common positions may, in the future, aid in the search. Duff and Murray[43] report that aberrant pancreatic tissue has been reported in 370 cases, located most frequently in the wall of the duodenum (30 per cent), stomach (26 per cent), jejunum (18 per cent), ileum (13 per cent), and other rarer sites such as the gallbladder, spleen, liver, mesentery, and omentum. It seems obvious, according to those authors, that islet-cell tumors may be expected to occur rarely in one or another of these situations. Holman, Wood, and Stockton[7] report a case in which an intrapancreatic adenoma was removed and at a later operation an extrapancreatic adenoma was found. They also refer to another case in which, at necropsy, an islet-cell adenoma was found as a submucosal nodule of the duodenum. In the second case which we are presenting the carcinoma was believed to have arisen from aberrant pancreatic tissue in the liver.

The most frequent location of islet-cell adenomata is in the tail of the pancreas, but 25 per cent occur either in the head or at the junction of the head and body of the pancreas. Two or more islet-cell tumors may be present at different places in the same pancreas, as is evidenced by the fact that multiple adenomata have been found in 12 per cent of the cases. Spangler reports such a case,[37] in which three separate adenomata were removed with cure of the symptoms.

Gray,[6] in a review of nine proved carcinomata with metastases, reports that metastases were localized in the liver, mesenteric lymph nodes, and epicardium. In the case described by Gray, there was definite basophilism of the pituitary gland. This phenomenon has been described previously in cases of islet-cell adenomata with hypoglycemia. In Friedman's two cases[44] there was marked basophilic adenomatous hyperplasia of the anterior lobe of the pituitary gland and marked obesity.

Conn and Conn[21] present numerous metabolic studies by which they classify, from the point of view of clinical behavior, the various causative types of spontaneous hypoglycemia into two broad groups, namely, the stimulative hypoglycemias and the fasting hypoglycemias. The best example of the stimulative type is that condition designated as functional hyperinsulinism, in which a precipitous fall of the blood sugar to hypoglycemic levels (40 mg. per cent or below) follows the ingestion of large amounts of carbohydrate. The level of the fasting blood sugar, however, remains normal even when dietary carbohydrate is restricted. A reduction in the carbohydrate content of the diet controls the episodes of transient postprandial hypoglycemia. The fasting type of spontaneous hypoglycemia is well illustrated in cases of certain kinds of severe hepatic disease in which restriction of dietary carbohydrate produces a low level of the fasting blood sugar. A diet high in carbohydrate controls the fasting hypoglycemia. These authors point out that organic hyperinsulinism appears to include both these types. A low level of the fasting blood sugar is always found, and restriction of the carbohydrate of the diet depresses it farther. In this sense the condition may be classified as a fasting hypoglycemia. At the same time, however, a stimulative effect is seen in the fact that two to four hours after a meal the level of the blood sugar is frequently far below that observed in the postabsorptive state.



Case Reports

Case 1.—C. P., a 38-year-old married Greek woman, came to the hospital in an unconscious state in July, 1944. The history as obtained from the husband was that the patient was in her usual good health until three years prior to admission, at which time she began to have fainting spells. These episodes would usually come on around meal time and only if the patient delayed eating for one half-hour to one hour beyond the usual time. The fainting would be preceded by feelings of anxiousness and apprehensiveness and generalized tremors. If she were able to eat some food in time, the fainting attack would be avoided. She noticed that the attacks were mild at first and usually lasted from ten to thirty minutes, but as the disease progressed these attacks would often last one to two hours and would usually cease spontaneously. Nineteen days before admission she had an attack lasting two hours and on the evening of admission she had been unconscious for a period of four and one-half hours before being brought to the hospital. She averaged from four to eight attacks a year for the past three years and her husband stated that sexual intercourse would precipitate these episodes on occasions. It was revealed by further questioning that the patient had been treated for anxiety neurosis and for epilepsy by another physician for the past three years.

Physical examination at the time of admission revealed that the patient was a well-developed, well-nourished white woman of about the stated age who was comatose and could not be aroused. Her temperature was 97 F., pulse 70, respirations 28, and blood pressure 100/68. The skin was clear throughout. The patient tended to stare straight ahead and the pupils were fixed to light and accommodation. The fundi were normal. A soft systolic murmur which was not transmitted was present at the apex. The lungs and abdomen were negative. Pelvic examination revealed a markedly retroverted uterus, a long cervix with an irregular external os which admitted one finger. The adnexa were negative. The rectal examination was negative. All reflexes were physiologic. The admission impression was hyperinsulinism due to a probable adenoma of the islet cells of Langerhans. The patient was given 50 cc. of 50 per cent glucose intravenously

shortly after admission and within two minutes sat up in bed and began to carry on a conversation with her husband.

Laboratory Data: The blood Kline test was negative, blood urea nitrogen was 18 0 Urinalysis: sp. gr. 1 007, acid reaction, negative albumin, negative glucose, occasional white blood cells and a few epithelial cells. A fasting blood glucose was reported

phonuclears 69 per cent, transitional 8 per cent, lymphocytes 21 per cent, and monocytes 2 per cent

During her hospital stay the patient was given a high carbohydrate, high protein diet and sedation At no time did she have a fainting attack, even when the fasting blood glucose dipped to 26 mg per cent.

The patient was discharged from the hospital on July 22, 1944, after arrangements had been made for her to be admitted to the surgical service of Dr. Allen O. Whipple at the Presbyterian Hospital, New York.

She was admitted to the Presbyterian Hospital on July 24 Physical examination showed a temperature of 100 2 F , pulse 85, respirations 20, blood pressure 115/72 She was moderately obese, extremely lethargic, and phlegmatic Fasting blood sugar was 30 mg. per cent The same tentative diagnosis was made and she was operated upon on July 28.

At operation, a tumor was found situated on the posterior aspect and in the middle of the lower border of the body of the pancreas This tumor, on section, had the appearance of an adenoma with very little if any fibrous degeneration in it, and a frozen section was pronounced to be a typical adenoma by Dr. V. K. Frantz.

Postoperatively the patient's fasting blood sugar rose to 98 mg. per cent. The patient was discharged as improved on August 10 She returned to Lincoln Hospital on September 8 and a glucose tolerance test (Exton-Rose technic) showed a fasting blood glucose of 87 mg. per cent, one-half-hour level of 91 mg. per cent, one-hour level of 96 mg per cent, and a one and one-half-hour level of 87 mg per cent

Case 2.—N. R , a 53-year-old man, entered the hospital on February 7, 1940, in an unconscious state and the history was obtained from the patient's brother, who stated that on the morning of admission the patient felt dizzy while dressing and then lost consciousness, frothed at the mouth, and had some spasticity of the right upper extremity. He never had had any previous attacks but he did notice profuse perspiration for about one month prior to admission This was relieved by drinking pineapple juice. He found that it became necessary to drink four or five glasses a night He also noted that he was ravenously hungry in the morning and was also mentally confused. This was relieved also by the ingestion of food. He found it necessary to eat frequently during the day to avoid episodes of weakness He was told eight months prior to admission that he had high blood pressure and a "slightly damaged heart" and was given pills to lower his hypertension (aspirin, phenobarbital, sulfuric acid, and atropine).

Physical examination revealed a temperature of

TABLE 1.—GLUCOSE TOLERANCE CURVE

Exton-Rose technic	Sugar	Urines Acetone	Diacetic Acid
Fasting 42 mg per cent	0	0	0
50 cc. of 50 per cent glucose			
1 hour, 81 mg per cent	0	0	0
2 hours, 167 mg per cent	0	0	0

98 6 F., pulse 78, respirations 34, and blood pressure 190/110 The patient was a well-nourished, well-developed, somewhat obese white man of about the stated age, lying quietly in bed in no distress. The positive physical findings were: perforated right eardrum without discharge; nasal septum deviated to right, turbinates enlarged and congested bilaterally; edentulous mouth; breath sounds diminished throughout the chest; heart enlarged to the left, a soft apical systolic murmur not well transmitted; abdomen negative—both inguinal rings were dilated; erythematous areas with silver-white scales were present on knees and elbows; reflexes were physiologic.

The admission impression was: (1) syncope, cause to be determined; (2) chronic catarrhal otitis media, right, (3) psoriasis, (4) hypertensive cardiovascular disease While in the hospital the patient had numerous attacks in which there was marked hyperactivity plus unconsciousness These lasted for about an hour at a time and in most of these the patient would have a temporary paralysis of the right arm and leg plus a left facial paralysis with absent right abdominals and positive right Babinski reflex. After cessation of the attack the paralysis and other neurologic findings would disappear. Blood sugar was 38 mg. per cent and it was then considered that hypoglycemia was the probable cause of the attacks Further attacks were treated with 50 cc of 50 per cent glucose intravenously with marked improvement in the patient's condition Repeated spinal taps revealed initial pressures varying from 140 to 180 mm of water with spinal fluid sugars of 49 to 55 mg per cent, proteins of 25 to 30 mg. per cent No cells were found at any time Nonprotein nitrogen was 39 0 and urea nitrogen was 15 8 The urine showed specific gravity of 1 020, acid reaction, negative glucose and albumin, and occasional urates The fasting blood glucose varied from 28 mg per cent to 52 mg per cent, with one too low to be read. Blood cholesterol was 200 mg per cent and the blood calcium level was 10 8 mg and 10 0 mg. The blood Wassermann was negative, hemoglobin was 92 per cent, red blood count 5,100,000, white blood count 8,900 with 70 per cent polymorphonuclears, 10 per cent stab cells, and 20 per cent lymphocytes. The basal metabolism rate was −2 ;

as

stricken with a convulsive seizure at 11:15 A M This started with a cry, there was rotation of the head and eyes to the right and a clonic convulsion beginning with the

feet, and ending wi

tremities with carp

lowed by a state c

Blood pressure was 170/90.

11.20 A.M. Blood glucose 118 mg per cent 50 cc. of 50 per cent glucose administered Carbon dioxide—28 volumes per cent.

11:22 A.M. Second convulsion occurred. Blood pressure 122/82.
11:32 A.M. Blood glucose 298 mg. per cent. 50 cc. of 50 per cent glucose administered. Carbon dioxide—22 volumes per cent.
11:38 A.M. Third convulsion occurred. Blood pressure 120/80.
11:48 A.M. Blood glucose 446 mg. per cent.
11:49 A.M. 5 grains sodium luminal given intravenously.
12:00 NOON. Fourth convulsion occurred while 35 cc. of 50 per cent glucose was being administered.
12:15 P.M. Spinal tap—initial pressure varied between 140 and 200 mm. of water, varying with respirations; it was crystal-clear. The spinal fluid sugar was 55 mg. per cent and the total protein was 25.0 mg. The urine had 1 plus sugar.
12:19 P.M. Fifth convulsion occurred, which was shorter than previous attacks.
12:30 P.M. 5 grains sodium luminal given intravenously.
1:40 P.M. 10 cc. of 10 per cent calcium gluconate intravenously. Patient sleeping quietly, pupils small, centered, and stationary. Blood glucose 266 mg. per cent. Blood calcium 10.8 mg. per cent.
2:40 P.M. Patient moving around, response greater than before and speech becoming intelligent; understands what is said to him. Blood glucose 127 mg. per cent.
3:40 P.M. Patient about the same. Blood glucose 67 mg. per cent. Calcium 14.8 mg.
5:40 P.M. No change in patient's condition. blood glucose 92 mg. per cent. Carbon dioxide combining power 36 volumes per cent.
6:30 P.M. Shows improvement. Understands what is said to him. Reflexes intact; no residual neurologic difficulties.
7:15 P.M. Urine 2 plus albumin; negative acetone; 1–2 plus sugar; reaction acid; sp. gr. 1.015. Occasional red blood cells and white blood cells.
8:30 P.M. Patient perfectly well, without neurologic difficulties.

It was the consensus of opinion of the neurologist and other members of the staff that the seizures which this patient experienced were really epileptic in nature because of a focus somewhere in the left cerebral hemisphere and it was also believed that the hypoglycemic attacks may have precipitated these epileptic seizures. It was decided to transfer the patient to Dr. Whipple's service at Presbyterian Hospital for exploratory laparotomy in the hope that an adenoma of the pancreas or some other pathologic lesion in the pancreas could be removed and thus alleviate these seizures. A chest film taken during the hospital stay revealed slight enlargement of the cardiac shadow in the region of the left ventricle and no evidence of pulmonary lesion. Skull films showed no evidence of lesions of the skull and the sella turcica was normal. A flat film of the abdomen failed to show evidence of any calculi in either urinary tract and there were no extraneous shadows in the abdomen. A gastrointestinal series revealed no evidence of any lesion of the stomach and duodenum. On the forty-sixth hospital day, just prior to transfer, it was noted that the liver was enlarged about 3 inches below the right costal margin and it was felt that possibly the patient had a malignant process in the pancreas which had metastasized to the liver.

The patient was operated upon at Presbyterian Hospital and exploratory celiotomy revealed the presence of an inoperable carcinoma of the islet-cell tissue of the pancreas with metastases to the liver.

Following operation the patient was discharged from Presbyterian Hospital and re-entered Lincoln Hospital, where he was observed for three weeks. During this time the patient had frequent episodes of sweating, all relieved by multiple injections of intravenous glucose. He was given a high caloric, high carbohydrate diet fortified by extra feedings and orange juice ad lib. Fasting blood glucose on readmission was 73 mg. per cent with a cholesterol of 200 mg. per cent, hemoglobin 80 per cent, red blood count 4,250,000, and white blood count 7,400.

At the end of three weeks the patient was transferred to Montefiore Hospital for chronic care. The patient continued to have frequent attacks of hypoglycemia which were controlled to some extent with sugar and epinephrine. His course was downhill and he contracted pneumonia and died. Symptoms began in December, 1939, and he expired on August 24, 1940.

Postmortem Anatomic Diagnosis

Carcinoma of islets of Langerhans arising in aberrant tissue in liver with metastases to spleen, myocardium (right ventricle), lungs, kidneys, skin, suprarenals, and hilar, mesenteric, retroperitoneal, and portal lymph nodes; infarct of lung (right upper lobe); chronic purulent bronchitis; bronchopneumonia (right upper lobe); and cholelithiasis.

Discussion

The first case was a proved adenoma of the islet cells but the second case, previously reported by Ballinger,[9] has not been accepted by many as being a true carcinoma of the islet cells with metastases because of the complex picture which the case presented. Kerwin, in his review,[22] discusses the usual cerebral changes produced by fatal hyperinsulinism and he states that as reviewed by Malamud, Grosh, and Baker, they include congestion, edema, hemorrhages, perivascular lymphocytic infiltration, cortical atrophy, degeneration of ganglion cells in the cortex and basal ganglia, degeneration of neurons, and encephalomalacia. Similar lesions have been produced in the experimental animals in some cases. It is our contention that this case was a true carcinoma of islet-cell tissue and that most of the complexity of the clinical picture with regard to neurologic signs when the blood sugars were normal was undoubtedly due to cerebral damage which the patient had suffered because of frequent episodes of hypoglycemia. This opinion is further substantiated by a report of a case by Campbell, Graham, and Robinson[29] in which the patient manifested dysarthria, incontinence, and evidence of psychosis following prolonged hypoglycemic states. These disabilities persisted despite a successful removal of an islet-cell adenoma with normal postoperative fasting blood sugars and glucose tolerance curves.

Summary

1. We have presented a review of the literature of islet-cell tumors and have collected 60 additional cases, 56 of which were benign, 4 malignant.

2. We have briefly discussed the physiology of hyperinsulinism. In addition there is presented a

summary of the more interesting cases in the literature of the past five years

3 This paper adds to the literature one islet cell tumor, a benign adenoma

4 This brings the total of islet cell tumors to 176 Of these, 127 are benign adenomata, 27 carcinomata, and 22 questionable carcinomata *

* The cases presented herein were from the medical service of Dr Robert L Hutton at Lincoln Hospital

We wish to thank Dr Allan O Whipple Dr V Kneeland Frantz and Montefiore Hospital for granting the permission to use some of the records presented above

To Dr Irving Kravetz Dr Leo Klinger and Miss Fanya Woll we are indebted for the laboratory facilities and excellent case study of our second case

CONTACT LENS SOCIETY FORMED

The society will aim to improve and promote research in and development of contact lenses, to establish a foundation for research in any or all

available to persons who are interested in the advancement of contact lenses and in their development

The board of directors is to consist of fifteen members three to be ophthalmologists, three optometrists three opticians, three contact lens technicians, and three contact lens manufacturers

thoritative information

Members of the organizing committee were Philip L Salvatori, New York, Ewing Adams, O D, Detroit, Albert L Anderson, Minneapolis, Phil E Dempsey, Toledo, Ohio, Dr Abraham Allan Rossby, New York, and Gertrud Salvatori, New York —*J A M A , Dec 16, 1944*

URTICARIA IN INFECTIOUS MONONUCLEOSIS—CASE REPORT

SELVAN DAVISON, Capt., (MC), AUS

(From the Medical and Laboratory Services, Station Hospital, Santa Maria Army Air Field, Santa Maria, California)

CUTANEOUS reactions in infectious mononucleosis are not rare, and have been frequently described. Tidy,[1] in 1934, strongly emphasized their role as a part of the syndrome of infectious mononucleosis. However, it is by far the rare writer who mentions the possibility of the occurrence of a true classic urticarial exanthem accompanying infectious mononucleosis, and this writer has not been able to find any case report describing such a combination. It is felt that the description of this case, together with certain observations, will be of interest and value.

H. Letheby Tidy,[2] in a later report (1937), said that early in the history of infectious mononucleosis the occasional development of ill-defined urticarial and erythematous eruptions had been briefly mentioned. However, he emphasized that the characteristic eruptions are similar to those occurring in such diseases as typhoid fever, typhus fever, measles, German measles, scarlet fever, erythema nodosum, and even chickenpox. The two main groups are a maculopapular and a morbilliform reaction. J. R. Paul,[3] one of the originators of the Paul-Bunnell test, speaks of the maculopapular and the morbilliform rashes but does not mention urticaria. Other observers,[4–7] in writing of the skin eruptions associated with infectious mononucleosis, fail to mention the urticarial rash. The writer has seen a great many cases of infectious mononucleosis at a large metropolitan hospital, and noted no urticarial reaction in any case. Sadusk[8] and Kracke,[9] emphasizing the maculopapular and morbilliform appearance of the eruption, incidentally mention the occasional and apparently rare appearance of urticaria. Sutton and Sutton,[10] in their exhaustive treatise on skin diseases, do not report urticaria as a finding in infectious mononucleosis.

Case Report

A 27-year-old white soldier was admitted to the hospital with a diagnosis of acute nasopharyngitis. Seven days before admission, there was an onset of frontal headache, moderate weakness, and evanescent chilly feelings. These symptoms were still present when he entered the hospital.

The past history was not unusual except that he had had hay fever all his life. The family history was not relevant. He had been in the Army for fourteen months. His home was in Milwaukee, Wisconsin.

The physical findings on admission were negligible. There was slight tenderness over the right frontal and right maxillary regions. The nasopharynx and pharynx were not inflamed. The heart and lungs were normal. The blood pressure was 120/72. The pulse was 80 per minute. The temperature was 101 F. orally.

It was considered that the patient had a mild sinusitis and treatment was instituted, beginning with steam inhalations. Several hours after admission the patient suddenly complained of a severe itching and noted a rash. On examination, the eruption was found to be a classic urticaria. The lesions were generalized, raised from the surface, and varied in size, many being over 2 inches in diameter. Some of the lesions were serpiginous and others were oval in outline. The centers were generally pinkish and many had a wide, raised erythematous peripheral zone.

No treatment except unmedicated steam inhalations had been given prior to the appearance of the exanthem.

A complete investigation of the patient's past history revealed no indication of a similar episode. He had received the following injections while in the Army: During January, 1943, he was vaccinated against smallpox, typhoid fever, and tetanus. He believes that as a child he was vaccinated against diphtheria. Absolutely no other injections had been received.

Two subcutaneous injections of epinephrine, V minims and X minims, respectively, were given several hours apart. Both times there was moderate fading of the rash and some alleviation of the pruritus. Simultaneously with the second dose of epinephrine, the patient had a severe reaction. He became pale, the pulse was almost imperceptible, and he was extremely faint. Within a few seconds complete recovery occurred.

Two days after admission, he complained of a sore throat. Examination revealed moderate pharyngeal injection. For three days after admission, the patient had several recurrences of the urticaria, each less severe than the preceding one. His headache disappeared.

A white blood count taken on the day of admission was 7,200 per cmm. The differential white blood count was neutrophils 51 per cent, stab cells 11 per cent, lymphocytes 33 per cent, and monocytes 5 per cent.

The white blood count the day after admission was 6,250 per cmm. The differential white blood count was neutrophils 33 per cent, lymphocytes 51 per cent, monocytes 13 per cent, eosinophils 2 per cent, basophils 1 per cent.

Two days later the white blood count was 7,500 per cmm. with 42 per cent neutrophils, 52 per cent lymphocytes, 5 per cent monocytes, and 1 per cent eosinophils.

The next day the white blood count was 10,600 per cmm., with neutrophils 18 per cent, lymphocytes 26 per cent, and monocytes and large lymphoid cells 56 per cent.

Five days later the white blood count was 13,350 per cmm., with neutrophils 26 per cent, lymphocytes 38 per cent, monocytes 24 per cent, and large lymphoid cells 12 per cent.

The Kahn test was negative.

A heterophile agglutination test done by the Ninth Service Command Laboratory showed a titer of 1:80. This was five days after admission.

Another heterophile agglutination test taken six days later showed a titer of 1:160.

The absorption test was done using guinea-pig

kidney and no change occurred, confirming the diagnosis of infectious mononucleosis

On physical examination at this time the tip of the spleen was palpable There was a moderate generalized adenopathy, and large, nontender, firm cervical nodes, mainly posterior, were particularly noticeable The patient's temperature was normal, and the only complaint was that he felt 'washed out"

A week after admission the spleen was palpable for one and one half fingerbreadths below the left costal margin Two weeks after admission the spleen became smaller, and the nodes diminished in size and number The patient felt well but still somewhat weak, as is common in most people convalescing from infectious mononucleosis A heterophile agglutination test taken one month after discharge from the hospital was 1 80 After an absorption test the titer was still 1 80

Discussion

Davidsohn,[11] in 1929, pointed out the existence of heterophile antibodies for agglutination of sheep red blood cells in serum sickness Paul and Bunnell[12] in 1932 showed the high titers of heterophile antibodies for sheep red-cells to be a diagnostic feature in infectious mononucleosis The Davidsohn absorption test enables one to differentiate between the high heterophile antibody titers found in infectious mononucleosis and in serum sickness In the latter condition the Forssman heterophile antibodies for sheep erythrocytes will be removed by absorption tests In infectious mononucleosis the heterophile antibodies are not removed Despite this differentiation, it is of interest, considering the occurrence of urticaria in infectious mononucleosis, to speculate on the relationships between this disease and serum sickness

In the case presented, the patient had been ill for seven days before the urticaria appeared On the day of admission, the only abnormal finding in the differential white blood count was the presence of 11 per cent young neutrophils (stab cells) This is reported by Erf[13] as not unusual in early stages of infectious mononucleosis The blood count was taken before the appearance of the eruption Thirty-six hours later another blood study showed a sharp reversal of the differential count, a marked lymphocytosis and monocytosis A possible relationship is apparent between (*a*) the prodromal seven days, the ensuing rash, the reversal of the blood picture, and (*b*) the seven to eight days it usually takes for serum sickness to appear As seen in our case, the patient had received no serum The vaccines and toxoids given seven months previously could not possibly have caused the urticarial eruption observed

Could some forms of the syndrome known as infectious mononucleosis be allergic in nature? Infectious mononucleosis is certainly a protean disease For instance, the characteristic heterophile or Paul-Bunnell reaction does not occur in every case Erf[13] mentions that 40 per cent of cases do not have a positive heterophile antibody reaction The different characteristics found in many patients with infectious mononucleosis, such as varying types of skin eruptions, occurrence of jaundice, the frequent finding of a positive Wassermann in many cases, etc, is further proof of the diverse nature of infectious mononucleosis While certainly not attempting to draw conclusions from one case, one cannot help, as in this case report, presenting the possibility of an allergic reaction manifesting itself by a generalized urticarial rash and a suddenly stimulated reticulo-endothelial system pouring into the blood an excess of indigenous white cells The latter cells are typified by large abnormal mononuclear forms (large lymphoid cells) found in infectious mononucleosis

The urticaria could have been a coincidental manifestation during the course of the infectious mononucleosis However, the differential blood smear on admission, well before the onset of the eruption, was essentially normal The very next day, after the urticaria had appeared, there was a complete reversal in the differential count Therefore, one can state without hesitation that the urticarial exanthem was in this case a manifestation of infectious mononucleosis

Summary

1 The rare occurrence of a generalized urticaria in infectious mononucleosis is presented

2 The possible relationship of infectious mononucleosis to serum sickness and allergy is discussed

3 It is suggested that infectious mononucleosis is a protean disease and that in at least some cases the causation may be allergic in nature

BETTER MEDICAL CARE FOR MORE AMERICANS—HOW BEST ACHIEVED?

(An address delivered at a Forum conducted by the Sections on Insurance and Drug, Chemical and Allied Trades Section of the New York Board of Trade, The Waldorf-Astoria, November 9, 1944)

DR. FREDERICK WILLIAMS, Bronx, New York

MR. MODERATOR, Members of the Committee, Fellow Participants, Ladies and Gentlemen: It is indeed a distinguished privilege and a real opportunity for me to be asked to participate in this forum on "Better Medical Care for More Americans—How Best Achieved?" I say this because I am a doctor, a doctor who is actually engaged in the practice of medicine. I treat patients! I am not a professional lay welfare worker. I am not a lay public-health educator. I am not an ambitious politician. I am not a theorist with a medical degree who has never practiced medicine but has drawn up some utopian plan from his own imagination and is anxious to win support of some foundation or some government agency to put over his scheme. In inviting me to present the view of the local practitioner I feel that your forum is rather unique. For most of the discussions of medical care recently have involved politicians, lay public-health educators, social workers, industrialists, economists, and rarely, and very rarely, doctors. Perhaps the old axiom of Mark Twain's, "The less you know about a subject the more you can talk about it," holds true in this instance. However, you have invited me, you must want my opinions, and I shall try to express them as clearly and concisely as I can in my allotted time.

At the outset I am anxious to make one important plea, and that is that all those interested in medical care take the time to ask the doctors for an opinion. Doctors have devoted their lives to medical care and they know the complexity of the problems. There are too many people who start off on a scheme of medical care and, because the medical profession does not go "whole hog" for it immediately, there is a prompt complaint that medicine opposes all progress. This is a very grave error. Let me say here and now that there is no phase of our modern knowledge which appreciates progress more than medicine.

But let us turn now to the subject of the forum: to discuss "Better Medical Care for More Americans." Let me first attempt to clarify the problem by calling your attention to a definition of medical care. Medical care is the care of the sick or the care of an individual who is ill. The prime factor in this care is the importance of having first an attending physician. This is the central focus from which spring all the offshoots which contribute to a concept of complete medical care. The additional factors are hospital service, nursing service, technical service, and pharmaceutic service. In all of your deliberations don't for one minute forget that the practice of medicine is still an art. In the laws of this State the practice of medicine is defined, and I quote the law: "A person practices medicine, within the meaning of this article, who holds himself out as being able to diagnose, treat, operate, or prescribe for any human disease." This is the legal definition of the practice of medicine in this state.

Therefore, I wish to fix finally in your minds that the practice of medicine is a practice of a profession by individuals the same as the practice of the ministry or the practice of law. We don't speak in terms of a concept of spiritual care or legal care and I wish to warn you against misunderstanding concepts of "medical care."

This practice of medicine consists of advising sick people on what to do to get well. This physician's service of medical advice to the ill—or the practice of medicine—is the basis of all medical care. This has been true down through the ages from the aboriginal medical man to the modern, scientifically trained physician of today, and will continue to be true long after we have all passed on. The other factors of medical care, such as hospital service, nursing service, scientific technical laboratory service, and pharmaceutic services, are all secondary, and should be resorted to only upon the advice of the doctor. Practitioners have felt that much of the misunderstanding of the problems of the care of the sick have arisen in the past decade or two because of a wrong concept of medical care. Great strides forward have been made by the application of facts from all of the basic sciences of chemistry, physics, and biology to aid the doctor in his diagnosis and treatment of disease. The doctor has been very busy all this time trying to keep abreast of this progress. It was his function

to know as much of the medical and scientific facts as he possibly could and then skillfully to apply his knowledge to the individual patients under his care. To do this was quite a task in these active years of scientific progress.

Public-health education, in the meantime, was left to others. Many lay people entered the field of public-health education. They were duly impressed with the scientific advances in medicine. Medical schools and teaching institutions began a practice of medicine in which all cases received complete technical "work-up" for investigation and statistical studies. This tremendous addition of science impressed those in the field of public-health education. As a result of this development, the scientific aspect of the technical factors of medical care was taken to the people as public-health education, which proved very popular in this age of technology. The idea has spread so fast and received so much "ballyhoo" that one would be led to believe that medical practice has been reduced to an exact science, such as mathematics. The science idea—of laboratory tests, of x-rays, of analyses, of electric tracings, of chemical blood tests, and of instrumental observations—has become so popularized that rarely do we hear much of the advice of the physician. It is a common experience for me to have people ask not, "How is the patient" or "What do you advise," but rather, "What was the chemical laboratory report of the blood sugar?" Every practitioner has had the experience nowadays of having a patient who once was told he had high blood pressure, come to the doctor and want to know what his blood pressure is. He does not seek advice of the doctor. He does not wait for the doctor to tell him what to do. This fear and fallacy was capitalized on at the recent World's Fair booth where they took one's blood pressure for ten cents. How much did the customers learn from this single fact? Absolutely nothing.

Gentlemen, I warn you we are heading for a nation of neurasthenics and hypochondriacs if we permit scientific medical generalizations to be taken to the people as medical care, instead of the advice of a physician who has examined a patient. This idea of science replacing the physician has spread to such an extent that now the legislators have seized upon it. The idea is being developed that every individual who does not have at his immediate disposal all the accessory services for a complete scientific work-up is receiving inadequate medical care. The doctors have been diligent in their efforts to bring the essentials to their patients. More and more hospitals are being built and more doctors are practicing medicine in limited fields as specialists. This is real progress in medical practice but still, in spite of all this, we hear the cry of *"inadequate medical care."*

Let me ask you to consider what adequate medical care is. This is a definition I wish someone would make for me. I defy anyone to define adequate medical care to the satisfaction of any community, no matter how large or small, if he is going to do it in terms of science or the accessory services of medical care. But if we consider medical care as consisting of the personal competence of the physicians in the community, it is not difficult to realize that the service rendered by Dr. Dafoe to the Dionne quintuplets was quite adequate. We all know the facts. He did not have all the appurtenances—the nickel-plated machinery—but he did render brilliant care because he was a good doctor. I hope that I have fixed clearly in your minds what constitutes medical care. I will repeat for simplicity and emphasis—medical care consists of the practice of medicine, or the advice of a personal physician to a sick patient. Accessories to medical care are: (1) hospital service; (2) nursing service; (3) technical service; and (4) pharmaceutical service. These accessories are without any value whatever unless they are provided under the intelligent direction of a competent physician.

With this concept carried in your minds, let us now consider the practice of medicine in the future. The practice of medicine in the coming years will continue as it always has through the centuries. There will still be sick people and they will still seek advice regarding their illness. For the most part they will seek the advice of physicians, and will definitely prefer the better-trained and more skilled practitioners. Many problems are bound to arise as they have in the past. Many unpredictable problems will most likely arise as a result of the economic and social upheaval which will follow this holocaust of war. There will most likely be problems of distribution of physicians, of provision of hospital beds, of bugeting of the costs of medical care, and many more which we have not thought of as yet. For me to attempt to stand here and try to offer to you a plan, even a possible plan, to cover these very complicated and complex problems for an entire country the size of ours, with its 130 millions of people, would be sheer nonsense. It is impossible! It cannot be done by me, by any one man, or any group of men!

From what the medical profession does know from experience and what I sincerely feel from my own humble practice in the profession, there are a few fundamental features of the practice which must be maintained if medicine is to continue in quality and progressiveness as it has in the past. Strangely enough these fundamentals

are also the fundamentals of our democratic American way of life. These basic fundamentals made American commerce and industry, and they also contributed in a vast measure to our medicine as we know it today. They are not new. But they are as vital and dymamic today as they were in the days of our revered George Washington and our revolution from tyranny. Freedom and liberty are the fundamentals to which I refer. Not freedom from anything—but freedom, just plain free!

In the practice of medicine, this freedom and liberty consists of: first, for all medicine, freedom and liberty from tyrannic bureaucratic political control; second, for doctors, nurses, hospitals, technicians, pharmacists, drug manufacturers, freedom and liberty of individual enterprise, and of individual competition; third, most important of all, for patients, freedom and liberty of choice of physicians and freedom and liberty to maintain the intimate personal relationship between the patient and his doctor.

If these few principles based upon our fundamental principles of American life are retained, I have no fear of the future and its problems. From these basic principles the "plan," if one can call it such, that I offer you, I draw from the natural science of biology; it is a plan of general evolution and local adaptation.

At the present time attempts are being made to budget the cost of medical care. From the practitioner's point of view the best solution seems to be voluntary insurance on an indemnity basis. This is a step in an evolutionary solution of the problem of costs. The practitioner feels that this will be sound, for it will not violate the basic principles of the practice of medicine which I have laid before you. Let come what may, we shall evolve a solution. It may well involve local state sovereignty for local adaptation throughout the country. But so long as it retains freedom and liberty, it will be the best in the world. If in the solution of any of these problems we deviate from these principles, medicine will survive, I am positive, but as to its progress or even maintenance of quality, I have very, very grave doubts. Let me remind you gentlemen that "the price of liberty is eternal vigilance."

HOW TO GET MEDICAL RECORD OF DISCHARGED VETERANS

Obviously, those who are being discharged from the armed forces and who are returning to civilian pursuits will at some time or other seek the advice of or treatment from physicians in civilian practice. In handling such cases, the civilian practitioner will be handicapped without a health and medical history of the person while he was in military service. Review of case histories is a fundamental requirement of good practice.

"What can I do in such cases?" the attending physician asks.

Here is the answer

The War Department has issued a regulation (No. 40-590) authorizing the commanding officer of any hospital where a member of the armed forces may have received treatment to release information from his or her medical record to "registered civilian physicians, on request of the individual or his legal representative, when required in connection with the treatment of the member or former member of the armed forces." It is stipulated that it is expected that the information given will be treated as confidential, as is customary in civilian medical practice.

It probably is safe to assume that the Navy Department and the Veterans Administration will cooperate in similar fashion.

Therefore, in dealing with exservicemen and -women, the attending physician should explain to them the need for this information, how it may be obtained, and suggest that the record be secured for his review so he will be better equipped to offer good advice and competent treatment. By doing so the physician will be benefiting the exserviceman or -woman as well as himself.—*Ohio State M. J., Nov., 1944*

FREE SYNAGOGUE HAS NEW MENTAL SERVICE

Patients discharged from the psychopathic wards of the city hospitals to the custody of relatives, and the families of patients committed to state institutions, will be studied and served by the newly established Mental Hygiene Committee of the Free Synagogue's Social Service Department. The committee began its work November 1.

The function of the committee, according to an announcement by Sidney E. Goldstein, director of the department, is to conduct an experiment to determine the existing needs, to examine available facilities, and to formulate a program that will adequately meet the needs in the Jewish community.

The new unit has grown out of the Free Synagogue's work with Jewish patients in the psychopathic wards of Bellevue Hospital.

"At the present time," Mr. Goldstein said, "little is known of what happens to the patients that are discharged to the custody of relatives, and a thorough study is necessary in order to learn the extent of unmet needs and the service that is required. Little is also done for the families of patients committed to the state institutions. In most of these families it is obvious there is need for study and education and adjustment. The governing principle in this work is that the family and not the individual is the unit of treatment."

The Mental Hygiene Committee, which will serve also as a center for advice, guidance, and, counsel, is located in the Free Synagogue House 40 West 68th Street, New York 23. The telephone number is TRafalgar 7-4050.—*Better Times, Nov. 17, 1944*

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL *The members of the committee are Oliver W H Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse), George Baehr, M D., and Charles L Post, M.D.*

Postgraduate Instruction for Cortland County Medical Society

POSTGRADUATE instruction, arranged for the Cortland County Medical Society, will be given Friday, February 16, at 8:30 P M at the Cortland County Hospital, Cortland, New York

Dr. Leo E. Gibson, professor of clinical surgery (urology) at the Syracuse University College of Medicine, will speak on the subject, "Infections of the Genitourinary Tract"

This instruction is presented as a cooperative endeavor between the New York State Department of Health and the Medical Society of the State of New York.

Hypertension

DR. WILLIAM GOLDRING, associate professor of medicine at the New York University College of Medicine, will lecture on "Hypertension and Hypertensive Heart Disease" at the Mercy Hospital,

---

ARTIFICIAL INSEMINATION

Sir: The letter from Dr. Harper in your issue of October 14 needs an answer It would have been well had he verified and weighed his facts rather more carefully before blossoming into print about this very complex subject of artificial insemination The following points must be made clear

Artificial insemination is certainly never done without the full and willing consent of the barren husband at any clinic or in any case with which I have dealings, nor, I imagine, would it ever be by any bonafide doctor in his senses Artificial insemination from a donor is called for only in a very small group of barren marriages (perhaps 2 per cent or less of all cases seen)—i.e., those in which the husband is completely and irremediably sterile and the wife fertile, where adoption is unacceptable because the wife desperately wants a baby of her own, and where, in consequence, the marriage may be in danger of breaking down In such cases, with the full and written consent of the sterile husband, artificial insemination, carried out as a private arrangement between the couple and the doctor, may be the best possible solution, leaving the world at large to regard the child as the husband's It is

[illegible]

the type who do not seek the easy way out of finding a "fancy man." It seems possible that there will be a better and more rational selection of genes if the wife receives an artificial insemination from a semen donor on a carefully chosen panel than if in her chagrin and desperation she commits an impetuous act of adultery. In any case, if we are to concern ourselves with the quality of genes there are plenty to engage our attention in the community at large before we concentrate upon that rare bird, the artificial donor Adoption undoubtedly is the solution for some, but an adopted child carries no genes from its adopted parents, whereas a child conceived as the result of artificial insemination does at least carry them from one.

In building up a panel of semen donors it is best to choose married men with offspring and to talk to their wives first, and only if these are willing for their husbands to act as semen donors are the husbands themselves approached. It is also well to select only those couples who appear to be intelligent enough to comprehend the reason for the appeal. (In the case quoted by Dr. Harper my judgment must have been at fault.) A clean bill of health, a sound intelligence, and a high grade of fertility are all essential in a donor; wherefore the building up of such a panel is no easy matter and places a grave responsibility on the doctor who attempts it In this help might well be given by such expert bodies as the Medical Research Council and the Eugenics Society.

The legal position with regard to artificial insemination from a donor has not yet been defined in this country. In America, where artificial insemina-

[illegible]

quires full [illegible] authorities however, [illegible] tection in this matter has not yet been voiced nor has organized religion committed itself

One last point. If by "veterinary" Dr Harper had meant scientific, which it is to be suspected he did not, it would have been a well-deserved compliment to the Cinderella of the professions—*Margaret Hadley Jackson, in Letters to the Editor of the British M. J., Oct. 28, 1944*

Medical News

WAC to Name Medical Unit for General Roosevelt

A COMPANY of the Women's Army Corps, chiefly medical technicians to stretch the care of returning wounded by meager Army nurse units, is being formed in honor of the late Brig. Gen. Theodore Roosevelt, Jr., and his wife has said of it: "I know my husband would consider this a great tribute. It is just the sort of living memorial he would appreciate."

With the participation of Mrs. Roosevelt and of men the general led in two wars, recruiting plans were announced at the apartment of Mrs. Lytle Hull in the Hampshire House, 150 Central Park South. General Roosevelt, once gassed, twice wounded, and twenty times decorated, died of a heart attack induced by exhaustion, with assault troops in the Normandy invasion on July 12.

Since time to train enough nurses is lacking, the Army plans to station WAC medical technicians in every hospital having 1,000 or more beds. It hopes to build the General Theodore Roosevelt, Jr. WAC Company quickly to a strength of 500, according to Lt. Col. Eric Johnson, assistant chief of the WAC Planning Branch, United States Army, Washington. An intensive drive to recruit the new unit in New York, New Jersey, and Delaware started February 1.

Mrs. Oswald B. Lord, chairman of the 2d Service Command civilian advisory committee for the WAC, announced this fact.

The Wacs will perform such ward services as taking temperatures, shaving the wounded, and keeping records, thus freeing nurses for other duties. More important, explained Captain Gill Robb Wilson, aviation editor of the New York *Herald Tribune*, they will provide "the feminine presence" which is essential to rehabilitation.

General Kirk Supports Nurse Draft Bill

ARMY hospitals in this country are receiving 30,000 to 32,000 patients monthly from foreign war theatres, as compared to 8,500 a month in the first half of 1944, Maj. Gen. Norman T. Kirk, surgeon general of the Army, testified today before the House Military Affairs Committee, in support of legislation to draft nurses.

This increase in the number of casualties, which includes the battle of the "bulge" in France, has caused the patient load in hospitals to rise in double the number of those being released, he added. Nearly 15,000 patients monthly, according to the general's testimony, are leaving Army hospitals to be returned to duty or to be discharged from the service.

Since May, "our patients requiring nursing care have increased from 260,000 to 450,000," but in the same period, despite appeals, there has been an increase of only 2,000 in Army nursing personnel, General Kirk pointed out.

"The increasing number of battle casualties, added to those requiring hospitalization because of sickness and disease, have greatly increased the demand for nurses," he continued. "American soldiers are entitled to, are receiving, and will receive the best medical care we are capable of giving."

The Army must have nearly 60,000 nurses at this time to furnish adequate nursing service to the soldiers. There are only about 42,000 women in the Army Nurse Corps as a result of volunteering, although "many others have volunteered but have been unable to meet the physical and other requirements," General Kirk said.

Actually, Army hospitals in this country are understaffed, he reported, because at least 60 per cent of the Army Nurse Corps are used to fill the minimum overseas requirements of one nurse for every twelve hospital beds. In this country the minimum requirements call for one nurse to every fifteen beds.

He explained that these requirements accounted for his stipulation of an additional 18,000 nurses, since the ratio in general hospitals at home is in practice one nurse for every twenty-five beds and there is need for additional nurses for overseas duty to assure the maintenance of the one-to-twelve ratio. Furthermore, many nurses have served in foreign theatres for a long time and should have an opportunity for rest, he added.

On the basis of increasing casualty lists and insufficient response to volunteer appeals, General Kirk declared that the additional number of nurses could be obtained only by extension of Selective Service legislation, particularly in view of the Army's experience last year.

General Kirk gave his approval to the continuation of the program of obtaining Army nurses on a voluntary basis, and conceded that it might be possible to obtain in this way a large proportion of the number needed.

Following General Kirk's testimony, the committee went into executive session to hear Maj. Gen. George F. Lull, deputy surgeon general, who supplemented his statement with detailed charts and statistics showing the development of the Army Nurse Corps.

The Representative explained that it was not intended to keep inducted nurses at the level of privates, but to raise them to the rank of second lieutenant in the Army of the United States after their induction, even though they might be drafted technically as privates. This view was supported by General Kirk.

American College of Surgeons Defers War Sessions

THE American College of Surgeons has deferred for the time being its 1945 series of War Sessions, four of which were to have been held in February, according to an announcement by Dr. Irvin Abell, Chairman of the Board of Regents. Dr. Abell states that plans had been completed for the February meetings because earlier indications were that sessions of a strictly educational nature, limited to relatively small local areas, would be sanctioned by the War Committee on Conventions, but

it now develops that the transportation crisis is so

plies

The American College of Surgeons has voluntarily omitted its annual Clinical Congress ever since the United States entered the war, in order to aid the war effort by minimizing the demands upon transportation facilities The War Sessions were devised as a wartime expedient to preserve the educational values in so far as possible with greatly lessened de-

rvices

to have been held in

isville on February 5,

, and in Cleveland on February 27.

Parran Outlines Health Insurance

DR THOMAS PARRAN, surgeon general of the United States, outlined a broad public-health program based on social insurance in a speech January 19 in observance of the dedication of the new $120,000 United Automobile Workers, CIO, Health Institute.

"It is obvious," he said, "that the financing of medical care of the individual, as a part of the program for total health care, should include some arrangement for prepayment"

The health program which he outlined would possibly be based on a combination of insurance and

tics, even though these smaller units were used primarily as emergency or feeder units for larger hospitals

The program should also assure "adequate numbers of health and medical personnel," and tax funds should be made available for the expansion of professional education, he said.

He advocated full-time Health Departments in

institutions He called for improvement in the country's sanitary facilities by means of the construction of public water and sewage systems

National Research Foundation Awards Medals

MEDALS for distinguished research during the year 1944 have been awarded by the National Foundation for Eugenic Alleviation of Sterility, Inc, to Dr John Rock and coworkers of Brookline, Massachusetts, for achieving fertilization of the human ovum in vitro and carrying it to the three cell stage, and to Drs Waldo B Edwards and Robert A Hingson, Surgeons, United States Public Health Service, for their achievements in continuous caudal analgesia in obstetrics

Consultation Service Psychiatric Conference Held by Army

THE first Consultation Service Psychiatric Conference was held at Aberdeen Proving Ground, Maryland, January 8, 9, and 10 In addition to the consultation service psychiatrists, representatives from each of the Army training centers also attended The purpose of the meeting was threefold to discuss common problems and procedures, to standardize techniques and procedures in the various consultation services, and to better acquaint the consultation service psychiatrists with recent and contemplated changes in War Department policy. Discussions emphasized prevention rather than treatment

Officers from the Surgeon General's Office who

illiam C

sychiatry

Q. Brill, MC, Chief of the Psychiatry Branch, and Capt. John W Appel, MC, Chief of the Mental Hygiene Branch

Army Neuropsychiatric Nursing Schools

NEUROPSYCHIATRIC nursing schools are now in operation in five service commands, and within the next few months will be established in all service commands in the United States These schools offer a three-month, on-the-job training course under the country's leading neuropsychiatrists

Enrollment is made up of Army nurses who volunteer for the training, and a certificate of neuropsychiatric nursing is awarded each on completion of the course At least two neuropsychiatric nurses are assigned to each general hospital in this country and to the staff of each general hospital organized here for service abroad

County News

Albany County

Dr Edward S Rogers, assistant state commissioner of

"modera-

Club, a

oup dis-

Freund,

representing the county society; Arthur Shepard, of the Equitable Assurance Company of America, and Milo Lathrop, Schenectady, field director of the Union for Electrical Workers

Bronx County

The regular meeting of the county society was

held at Burnside Manor on January 17 at 8:30 P.M. Following the executive session Dr. Arthur M. Fishberg spoke on "High Blood Pressure and Its Treatment," with discussion by Drs. John Duff and David Greenberg.

Chemung County

Chemung County's goal in the March of Dimes campaign was repayment of the $30,000 received last year from the National Foundation for Infantile Paralysis for care of polio patients.

The quota was set by the Chemung County Chapter, which also announced appointment of Oscar F. Kerlin as chairman of a special infantile paralysis educational committee.

Mr. Kerlin appointed personnel of the new committee which included representatives of public and parochial school health departments, members of teaching staffs in local nurse training schools, a representative of the Chemung County Medical Society, and a county school nurse.

The aim of the committee is to utilize educational material available and to expand winter and summer programs for handicapped children.*

Dutchess County

A meeting of the county society was held in the Pavillion of the Hudson River State Hospital on January 10 at 8:30 P.M.

Colonel Gillespie, of the British Army, spoke during the scientific session on "Interchange of Medical Ideas between the U.S. and British Armies: the Newest in Army Medicine."

Erie County

Preliminary arrangements for its annual campaign for funds with which to carry on its projects in Palestine have been virtually completed by Buffalo Hadassah, Women's Zionist organization. The campaign was inaugurated at a meeting January 13 in the Niagara Room of the Hotel Statler. Mrs. Moses P. Epstein, of New York City, National President of Hadassah, was the principal speaker.

For many years Hadassah has helped finance the famed Hadassah-Rothschild-University Hospital and Medical Center on Mt. Scopus in Jerusalem.

To this year's budget in connection with this undertaking has been added the construction cost of a Tuberculosis Surgical Wing and a 250-bed tuberculosis sanatorium at the hospital, the purchase of x-ray units and laboratory equipment, and the institution of an occupational therapy program for cured patients.*

. . .

A young Buffalo physician who thought he had been on every possible type of mission during his days as an intern at Emergency Hospital is believed to be the first doctor in the United States to use a helicopter to reach an injured man.

He is Dr. Thomas C. Marriott, resident physician at Bell Aircraft's Niagara Falls Plant, who was flown by helicopter to the aid of Jack Woolams, Bell's chief test pilot, who was snowbound in a farmhouse near Lockport where he had walked after bailing out of a P-59A Airacomet.

The helicopter was summoned from the Bell facilities at Gardenville after Dr. Mariott's ambulance became stalled in snow-clogged Transit Road.

"My brief trip in the Bell helicopter was only my third airplane ride," the physician said, "and I can see where the helicopter can be invaluable in situations like the one which confronted us."*

Greater New York

The seventy-seven voluntary hospitals in New York City were asked by Dr. Edward M. Bernecker, Commissioner of Hospitals, to admit alcoholics who are not mental cases, the commissioner said on January 4. He asked them to accept his proposal by January 15 when the thirteen general hospitals operated by the department start admitting this type of drinker.

Their acceptance of the plan, Dr. Bernecker said, would help take the load off the city institutions, which heretofore was carried almost wholly by the psychiatric division in Bellevue Hospital. If the voluntary hospitals refuse, he said, they will be asked to send alcoholics to the nearest general hospital o the Department of Hospitals in their district.

The new setup went into effect in Bellevue Hospital on January 2. Dr. S. Bernard Wortis, director of the psychiatric division there, called it a "foresighted step." Only a minority of inebriates accepted over the years by the alcoholic ward in his division needed psychiatric care, he said.

The magnitude of Bellevue's alcoholic work was shown by the Department of Hospitals through the number of admissions for this cause. In 1942, 10,575 persons were admitted for alcoholism; in 1943, 8,105, and in 1944, 8,562.

For many months the hospitalization committee of Alcoholics Anonymous, the organization of alcoholics which has helped others to control drinking, has advocated cooperation by the city's hospitals in the care of persons suffering from alcoholism. So far, allocations of from ten to fifteen beds have been made in two semiprivate hospitals.

Dr. Bernecker said, "A lot of alcoholics are not psychiatric cases and there's no reason why they should not be treated in the medical wards of the department hospitals."

"It's a lot better than putting them in jail, which is what happens to them in many other cities," Dr. Wortis said. "They are sick people and they must be treated like sick people. The change will mean better care. Alcoholism will be treated in the medical wards like any other medical problem."

Most of the alcoholics free of mental illness have other illnesses, said Dr. Salvatore Cutolo, deputy medical superintendent of Bellevue. As with all other patients, they will be given a complete physical examination and, if necessary, hospital care will start immediately, Dr. Cutolo said. Because of their duties with their specialty, he said, the Bellevue psychiatrists have been unable to do this.*

. . .

James M. Cecil, an advertising executive, will head the Committee of Public Information of the Red Cross 1945 War Fund Drive of Greater New York, which will be started on March 1, it was announced by Walter L. (Red) Barber, city-wide chairman of the campaign.

Mr. Cecil has served in the same capacity in three previous Red Cross drives. In addition, he is chairman of the Committee on Public Information of the New York chapter of the Red Cross. In 1942 he was public-relations chief for the United Service Organizations campaign.

Vice-chairmen of the committee are Samuel D. Fuson, vice-president, Arthur Kudner, Inc.; Clarence L. Law, vice-president, Consolidated Edison

The New York University College of Medicine has announced three postgraduate courses which started in February. One on internal medicine is given by Dr. Charles H. Nammack and his associates. One on clinical gastro-enterology, conducted by Dr. Zachary Sagal, was designated for practicing physicians. The lectures are preceded by demonstration of patients in the wards. The third course is conducted by Dr. Otto Steinbrocker on arthritis and rheumatic disorders. Additional information may be obtained from the secretary of the New York University College of Medicine.

• • •

The Bronze Star Medal was recently awarded to Capt. Samuel S. Pasachoff, formerly of New York City. The citation read "For meritorious service in connection with military operations against the enemy as general surgeon, 45th Evacuation Hospital, Semimobile, from Nov. 24, 1943, to Aug. 1, 1944 in England and France. Captain Pasachoff performed skillful operations on wounded soldiers, often going for long periods without rest or relief. In addition he designed and constructed numerous surgical articles which proved highly essential to the efficient operation of the hospital. The professional skill, ingenuity, and devotion to duty displayed by Captain Pasachoff reflect credit on himself and the military service."

• • •

Columbia University College of Physicians and Surgeons has received a grant of $14,500 from the Commonwealth Fund of New York to be applied to the study of respiratory physiology in the department of medicine.

• • •

Dr. L. Everard Napier, formerly director of the School of Tropical Medicine of Calcutta, India, was appointed visiting professor of tropical medicine at the New York University College of Medicine for the months of January and February of 1945. This was made possible by a grant received from the Commonwealth Fund. During this time Dr. Napier gave several special lectures to the faculty and student body and held conferences with students.

• • •

The Association for the Advancement of Psychotherapy met on January 26, at 8:30 P.M., in the Academy of Medicine Building. Drs. Anthony Bassler, Samuel Weiss, and Franz J. Lust spoke on selected borderline topics in gastro-enterology and psychotherapy, followed by general discussion and election of officers.

• • •

Dr. J. Burns Amberson was re-elected president of the New York Tuberculosis and Health Association at the annual meeting of the Corporation and the Board of Directors held on January 22. Other officers elected were Dr. Edward P. Eglee, first vice-president; Mrs. Myron I. Borg, second vice-president; Daniel Paul Higgins, secretary; and Raymond Atkin, treasurer.

Elected to serve on the Executive Committee were Dr. Donald B. Armstrong, Dr. George Baehr, Bailey B. Burritt, Dr. William B. Dunning, Dr. Edward P. Eglee, Dr. Kendall Emerson, Mr. Daniel P. Higgins, Dr. James Alexander Miller, Dr. Harry S. Mustard, Dr. H. McLeod Riggins, Mrs. Ruth Logan Roberts, and Dr. Amberson, ex officio.

Representatives to the Executive Committee from the Association's branches in the Bronx and Staten Island will be appointed by the president.

Elected to serve on the Council of the Tuberculosis and Health Associations of Greater New York, which includes the New York, Brooklyn, and Queensboro tuberculosis and health associations, were Alfred C. Howell, Dr. Riggins, and Winthrop A. Wood.

Dr. Edith M. Lincoln and the Hon. Newbold Morris are new members elected to the Board of Directors in the class of 1948. Re-elected in this class are: Dr. Armstrong, Mr. Atkin, Dr. Baehr, Mrs. Borg, Dr. Leverett D. Bristol, Dr. E. H. L. Corwin, Dr. Louis I. Dubin, Dr. Dunning, the Hon. Albert Goldman, the Very Rev. Msgr. William R. Kelly, Dr. Foster Murray, Dr. George G. Ornstein, William C. Thompson, and William O. Van Velson.

Also elected to the Board of Directors were Dr. Edward M. Bernecker, Commissioner of Hospitals,

Dr. Joseph Golomb, Dr. Harry S. Mustard, and Dr. C. C. Wilson.

The annual all-day conference of the Association was held at the Hotel Pennsylvania on February 7.

COMMISSIONER STEBBINS MAKES ANNUAL REPORT ON NEW YORK CITY'S HEALTH

"The year 1944 registered for New York City its lowest maternal mortality rate, and new low death rates were attained for tuberculosis, appendicitis, whooping cough, auto accidents, other accidents, and suicides," says Health Commissioner Ernest L. Stebbins in his annual summary report, submitted to Mayor F. H. LaGuardia. "Taking into account the impact of war conditions," states Dr. Stebbins "the health of the city was remarkably good in the year just closed."

He continues, "The city's general death rate for 1944 of 10.3 per 1,000 population was lower than in 1943 (10.9 per 1,000 population) and was only four-tenths of a point higher than the record low of 9.9 set in 1941. In 1942 the general death rate was 10.0 per 1,000 population.

"Deaths due to childbirth have decreased by almost two-thirds of what they were only about one decade ago. The maternal mortality rate in 1944 was 1.8 per 1,000 live births as against a rate of 2.2 in 1943. "Diphtheria was again reduced. Thirty years ago (in 1914) 1,491 persons died from this disease in the city. In 1944, with a population of 2,500,000 more people, only seven died from this cause.

"The city's birth rate for 1944 of 16.0 per 1,000 population was below the rates of 1943 and 1942, but otherwise was the highest since 1931."—*Release from the New York City Department of Health*

TRANSMISSION OF INFANTILE PARALYSIS

"The method of transmission of the virus of poliomyelitis," the *Journal of the American Medical Association* for October 21 says in answer to a query, "has not yet been clearly demonstrated. . . . . The virus has been found consistently in the alimentary tract and stools of both patients and contacts. While a large body of circumstantial evidence supports the theory of direct contact from patient to patient, there is also the fact that the virus has been recovered repeatedly from flies trapped in epidemic areas. However, the importance of the fly as a vector has not yet been clearly demonstrated. It is not possible in the present state of knowledge to say whether the contamination of the fly with virus is a result of a disease or a causal factor in it. The seasonal incidence of . . . . epidemics, combined with the finding of virus in the human alimentary tract, stools, sewage, and flies, lends weight to the contention that poliomyelitis is primarily an intestinal disease such as typhoid and dysentery. . . . . "

Hospital News

Army and Red Cross Ask Civilian Nurses to Give Their Day Off to Army

A SYSTEM under which graduate nurses classified as essential in civilian position or otherwise ineligible for military service will be asked to do volunteer duty at Army hospitals and ports of debarkation on their days off has been worked out by Army and Red Cross officials.

The volunteer nurses will be used chiefly for emergency duty, and will supplement paid civilian nurses now employed full-time in Army hospitals, Lt. Arthur M. Currier said at the headquarters of the chief surgeon of the 2nd Service Command, on Governors Island.

Lieutenant Currier, who is in charge of the command's new nurse procurement center at 39 Whitehall Street, has revealed that the Army has been employing civilian nurses to work at hospitals near their homes on a civil service status since November. These nurses, like the volunteers, must be ineligible for military service, either because they are more than 45 years old, have children under 14, or for other reasons.

While the qualifications of the paid civilian nurses are passed upon directly by the Army hospital to which the nurse applies for work, or by the chief nurse of the service command in which she lives, the volunteer nurse will be recruited only by the Red Cross, at 2 East 37th Street, Lieutenant Currier said.

Halloran General Hospital on Staten Island is employing as many civilian nurses as it can get and will welcome volunteer nurses to work for one or two days after the arrival of a convoy, Lt. Col. Jeanette Bletch, chief nurse, said.

There are 155 members of the Army Nurse Corps assigned to Halloran, Colonel Bletch said. In addition, the hospital employs fifteen civilian registered nurses not qualified for military service, and ten paid nurse's aides. Ten more civilian nurses are expected shortly, and in addition, the hospital expects about ten cadet nurse graduates. The hospital capacity is 6,000 patients.

Commenting on the Army's use of civilian nurses, Rear Adm. Edward U. Reed, chief medical officer of the 3rd Naval District, said recently that while some civilian nurses were being used in hospitals for Navy dependents it was not planned to expand this use. Underlining the urgent need for nurses in the armed services, the National Nursing Council for War Service revealed that during the month of December 1,000 sick and wounded servicemen reached this country daily, and predicted "the January rate may be higher."

Mental Hygiene Committee Helps State Hospitals Prevent Decline in Care and Treatment of Mentally Ill

THE National Committee for Mental Hygiene made public on January 21 a statement about what state hospitals for the care and treatment of the mentally ill can do to prevent "unnecessary decline" in the quality of their service in spite of wartime shortages of medical, nursing, and attendant personnel, of occupational therapy equipment, and of surgical and other facilities.

The Committee made inquiries of the superintendents of twelve state hospitals in various sections of the country as to what steps they were taking to meet the emergency. The report summarized the replies and suggestions for the benefit of other state institutions in the nation, which have an aggregate patient population of 600,000. The inquiry elicited the following, among other constructive suggestions to meet the current situation:

Select the best available personnel without political preference or favoritism.

Move for better salaries and working conditions to make the positions more desirable. This seems to have been generally done to a considerable degree. Emergency pay adjustment has been authorized in many places. Overtime has been paid when an employee has consented to lengthen the daily hours of work, or to forego vacation time, or days off duty. One hospital insists on at least two days a month off even if the employee would work longer. Retirement plans have been found helpful particularly with individuals who already have a substantial period of service to their credit.

Affiliate student nurses, Cadet Nurses, and courses for nurse postgraduate education have provided interested and capable workers. Wives of servicemen, some with nurse training, have been available in some localities. Conscientious objectors, where it has been possible to obtain them, are mentioned as of particular service. Employees have been recruited in less industrialized sections where state hospital wages appear more attractive. One hospital reports a great many people employed on part time.

Some hospitals have restricted medical service previously given to employees, as it conserves physicians' time and reduces the nursing load, but can hardly make the service more attractive.

Several hospitals say that attendants must be carefully placed at their work and suitably indoctrinated.

Employees engaged in direct care of patients should receive ample public recognition of the essential character of their services. Several have employed recovered patients for hospital service and others have permitted improved patients to sign their own parole, and have employed them at regular wages. They speak of it with reservations, but have found it more satisfactory than had been expected.

Suggestions were made to conserve physicians' time. These included definite office hours for physicians to see visitors, which leaves them otherwise free for ward duties; reduction of the number of visiting days; plans to have supervisors, nurses, and attendants alert to seek out and report to the physicians any appearance of illness; physicians and other staff members have increased their hours of duty by longer days and omissions of holidays

Patient of thin type of build—skeleton indrawn

ANATOMICAL SUPPORT for faulty BODY MECHANICS

In conditions of faulty body mechanics, the nonuse of the abdominal muscles allows the pelvis to rotate downward and forward, bringing the sacrum up and back. There results an increased forward lumbar curve with the articular facets of the lumbar spine crowded together in the back. The dorsal spine curves backward with compression of the dorsal intervertebral discs and the cervical spine curves forward with the articular facets in this region closer together. Therefore, chronic strain of the muscles, ligaments and joints of the spine and pelvis occurs.

Camp Anatomical Supports have an adjustment by means of which their lower sections can be evenly and accurately brought about the major portion of the bony pelvis. When the pelvis is thus steadied, the patient can contract the abdominal muscles with ease and then with slight movement straighten the upper back.

Relieving back strain and fatigue, due to faulty body mechanics is a feature of the Camp Support illustrated, and other types for Prenatal, Postnatal, Postoperative, Pendulous Abdomen, Visceroptosis, Nephroptosis, Hernia and Orthopedic conditions.

[Continued from page 424]

and vacations; reduced elective surgery; reduced clerical duties of physicians. One hospital has utilized part-time physicians from the community.

"Some hospitals have curtailed maintenance of buildings and machinery," the report said. Others point out the danger inherent in carrying such restrictions too far, speak for a good maintenance force, and commend the work of engineers and others for initiative and resourcefulness in the emergency.

Menus have received careful consideration of dietitians and food administrators, to simplify them, to provide and retain vitamins, and to find acceptable substitutes for rationed or scarce foods. Several hospitals have pushed production of food stuffs on their farms, and have done more canning and preserving.

Some institutions say that now is an appropriate time for reduction of a multiplicity of bureaucratic rules which tend to spring up and perpetuate themselves, and to eliminate what does not contribute directly to the welfare of the patients. When new duties and responsibilities are placed where they have not rested before, they should be accompanied by ample explanation, assistance, and supervision until the new duties are learned. It was advised that diagnostic and treatment services be maintained with prompt study and treatment of acute cases. Treatment begins in very disturbed or depressed cases on the day of admission, reducing the nursing difficulties formerly experienced and shortening the period of hospitalization.

One hospital reports that one of the most important factors in enabling them to carry on is the high morale and good and helpful spirit of patriotism which has been shown by the great mass of the employees and patients, realizing that during these times we must all buckle down cheerfully to make the best of conditions not previously existing.

Hospitals Begin Action on Health Needs of Nation

PRESENT hospital facilities were related to established and future health needs of the country by state hospital association officials in a two-day conference held by the American Hospital Association at Chicago's Drake Hotel, February 9–10. The Association's 3,500 member institutions—the majority of the voluntary hospitals of the country—took part in a program based upon a re-evaluation of the purposes of the hospital system.

The Association seriously considered pending federal assistance through grants-in-aid to hospitals for the vast program of growth necessitated by the expressed need for equitable hospitalization. A reference list of American architects who have had experience in hospital or institutional design and are qualified to assist in the widespread construction was presented by the Association's Council on Hospital Planning and Plant Operation.

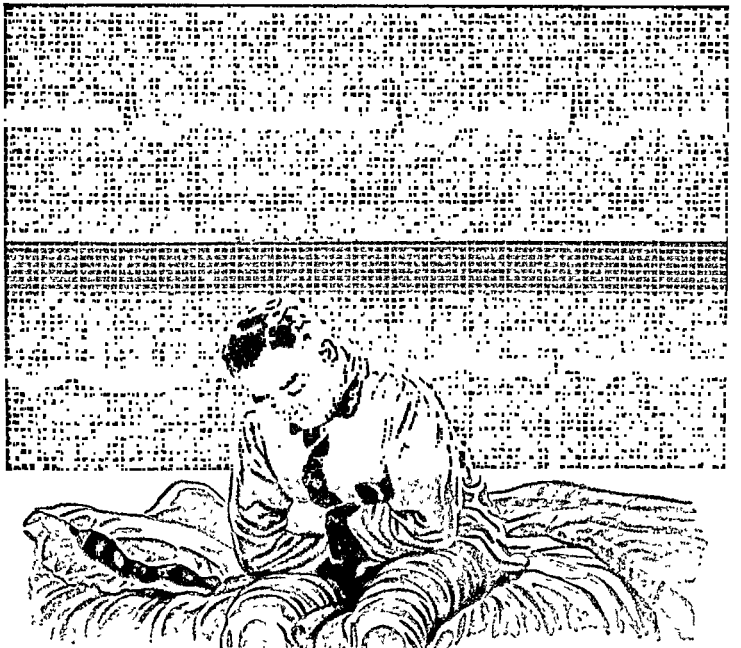
Fast-expanding health needs of the nation are currently being analyzed by eighteen leaders of labor, industry, education, science, agriculture, and religion, organized as the Commission on Hospital Care at the request of hospital members of the Association. Formulating plans for satisfying the increased demand for adequate hospital care of every segment of the population, the Commission, represented by Dr. Arthur C. Bachmeyer, director of study for the group and director of the University of Chicago Clinics, and Dr. Thomas S. Gates, chairman, president of the University of Pennsylvania, presented its preliminary findings and indicated courses of action to state groups ready to begin their regional analyses.

Surgeon General Thomas Parran of the United States Public Health Service was the speaker at a dinner given by the Association's Board of Trustees. Cooperating with the health service's recently launched $9,000,000 campaign for the eradication of tuberculosis, delegates will forward the American Hospital Association's own program of tuberculosis control and discovery in hospitals through programs of routine examination of patients and employees.

"The national emergency has made the hospital a more vital factor than ever before in the life of the American people," said Dr. Donald C. Smelzer, president of the A.H.A. "The public has awakened to the importance of the facilities offered by the hospitals in their communities and from now on it will demand more and better hospital care. Never before has there been such an opportunity for a service organization to increase its value to the public. The hospital must be more than just a place to house and treat the sick and injured. Hospitals are assuming a broader share of community responsibility."

Hospital Survey Opens Fight on Tuberculosis

CAUSING over half as many deaths since Pearl Harbor as the war itself, tuberculosis has become one of the world's greatest mortality factors.



That the hospitals of America may facilitate the eradication of human tuberculosis, 6,500 of them began participation in January in a survey inaugurated by the American Hospital Association to determine the number of institutions now examining their patients and personnel as a part of the regular admission routine.

"Of every 100,000 people in the United States in 1943, forty-four died of tuberculosis," stated Dr. Hugo V. Hullerman, secretary of the Association's Council on Professional Practice, which is making the survey. "Thousands of men and women never realized they had the disease until it had reached its incurable stages.

"Programs of routine examination have been found to discover 70 to 75 per cent of the cases in their minimal or primary stages. Without these precautions, as many as 90 per cent might go undiscovered. Hospitals in 1943 admitted over 27 million patients, and since one person in ten makes use of his hospital at some time during a year, a nationwide program of hospital examination would reach most of the country's population in a few years, including many who would not be included in employee surveys."

Results of the American Hospital Association survey will be used as a guide to hospitals and to state hospital associations in their future efforts, and as a measure of future programs for the continued improvement of the health care of the people in stamping out the disease which is striking yearly such a large percentage of the population.

Auricular Fibrillation

Rapid efficient digitalization requires a dependable, quick-acting digitalis preparation. These all-important characteristics are embodied in Digoxin, a pure crystalline glycoside obtained from the leaf of *Digitalis lanata*. It has the advantage of being a definite chemical substance, constant in composition and uniform in potency, and may be standardized by chemical methods and prescribed in terms of the weight of the pure drug.

Clinically, Rose, Batterman and De Graff[1] conclude: "Digoxin satisfies the established criteria for a reliable, potent digitalis preparation. The ventricular rate in patients with auricular fibrillation was controlled, and diuresis occurred in the majority of the rapidly digitalized patients within twenty-four hours."

Improvements

Re-establishment of the Catholic Charities Health Clinic for Children in Sisters Hospital, Buffalo, was announced on January 6 by the Rev. Eugene A. Loftus, director of Catholic Charities. The clinic had been functioning two months in temporary quarters in the hospital and now Sister Genevieve, superintendent, said it has been permanently established in the south wing of the building. Newly built doorways and partitions have unified the new section; there is a nursery-waiting room furnished with children's tables and chairs, dressing rooms, a weighing room, and a general examination room.*

• • •

Repairs are being pushed at the Smith Hospital, Oneonta, which was damaged by fire recently.

It was expected that patients would be received at the hospital by January 15, possibly sooner. The interior of the hospital structure was badly damaged by fire, smoke, and water.*

• • •

A campaign to purchase an iron lung for the Glens Falls Hospital was opened January 15 by the Glens Falls Council, 417, United Commercial Travelers, it was announced following a meeting of the council last night in the Queensbury. The council expected to complete the drive by January 25.

The obvious need for such life-saving equipment as the iron lung in a community as large as Glens Falls prompted the council to undertake the project. The campaign had the enthusiastic endorsement of hospital and medical authorities.*

• • •

Fourteen public-spirited North Tonawandans went to the new DeGraff Memorial Maternity Hospital on January 3 in spite of wind, snow, and cold, and waded into the dirt remaining on the second floor with mops and scrub-brooms. When the first 1945 Samaritan Squad had finished its tour of duty two hours later, it was reported that the second floor was completely cleaned and required only an application of wax before twenty-four expectant mothers' beds could be made up and patients accommodated.*

At the Helm

Annual reports of committees and election of officers featured the yearly meeting of the medical staff of the Olean General Hospital held at the Institution on December 19. Officers elected for the coming year are Dr. D. L. Wormer, president; Dr. L. J. Atkins, vice-president, and Dr. James F. Durkin, secretary and treasurer.

A résumé of the year's work was presented by Dr. A. L. Runals, retiring president.

The staff meeting was the first to be held under the new arrangement recently adopted, by which the time of meetings was changed from the third Friday night of each month to the third Tuesday afternoon of each month from noon until one P.M.*

• • •

Dr. George E. Taylor was elected chief of staff of Bethesda Hospital, Hornell, at a meeting on December 18. He succeeds Dr. Merle A. Place.

Other officers elected are Dr. Roger Haggerty, of Arkport, vice-president; Dr. Howard S. Brasted, secretary.*

• • •

Appointment of Mrs. Irene E. Oliver, of South Weymouth, Massachusetts, as superintendent of Tompkins County Memorial Hospital, Ithaca, was announced on December 20 by Joseph S. Barr, chairman of the board of trustees.

A registered nurse and a graduate of a Massachusetts hospital nurses' training school, Mrs. Oliver for the last eighteen years has been administrator of Weymouth Hospital, Weymouth, Massachusetts. She is a member of the American College of Hospital Administrators, and a trustee of the Massachusetts Hospital Association.

During her administration, the capacity of Weymouth Hospital was increased from 20 to 170 beds, which is a larger bed capacity than Memorial Hospital. During her tenure at Weymouth, Mrs. Oliver has guided two building expansion programs.*

• • •

Six North Queens physicians were appointed to the courtesy staff at Flushing Hospital on December 19 at a meeting of the board of trustees. The appointees include Drs. Arthur Langstadt, Rudolph Ebert, Flushing; Henry Shankman, Kew Gardens; Thomas McCann, Elmhurst; and Edward Giovine, Woodside.

The trustees approved the reinstatement of Dr. Harvey Van Lammer as ophthalmologist and chief of the ophthalmologic clinic.

Dr. Van Lammer had been on leave from his duties at the hospital, while serving in the armed forces.

Mrs. Jean Smalbach, chairman of the nursing committee, reported that Gladys L. Nichols assumed the post of director of nurses and principal of the nursing school in December, 1944.

Official Referee John M. Cragen, acting chairman of the board in the absence of L. Gale Hunter, presided at the session.

The trustees paid tribute to a fellow member, Frederick W. Woppler, who has been making a detailed survey of the hospital and its equipment, and has suggested repairs and renovations.*

• • •

Dr. A. J. Roach, for the past twelve years superintendent of the Broome County Tuberculosis Hospital, took over the duties of superintendent of the Montgomery Sanatorium December 1. Dr. Roach is well qualified to serve in this administrative capacity, having had a wide experience in New York, Massachusetts, and Wisconsin.*

Col. G. G. Duncan, MC, formerly Chief of Medical Service at Thomas M. England General Hospital, Atlantic City, New Jersey, has been assigned as Consultant in Medicine, Headquarters, Second Service Command, Governor's Island, New York. He replaces Lt. Col. Herrman Blumgart, MC, assigned overseas.

• • •

Dr. A. T. Goldstein was elected president of the staff of St. Luke's Hospital, Utica, at its annual meeting held January 4 in the hospital.

Other officers elected for the ensuing year were: vice-president, Dr. C. S. Dickson; secretary-treasurer, Dr. A. Vernon Johnston, and executive committeemen, Dr. John Gromann, Dr. Herbert W. Thomssen, and Dr. William H. Williams.

Dr. Fred G. Jones presided. Hospital records and case histories were reviewed.*

• • •

The Rev. Clarence L. Braun, for thirty years superintendent of St. John's Lutheran Orphanage, Buffalo, has been appointed superintendent of DeGraff Memorial Hospital in North Tonawanda.

Harry C. Jagow was named trustee of the DeGraff Memorial Hospital at a special meeting of the State Trust Company directors on January 4 to fill the vacancy on the hospital board left by the resignation of Chairman Dow Vroman.*

• • •

Dr. Cecil E. Pitard has assumed his new duties as resident physician in the Kingston Hospital. Dr. Pitard has just completed his internship at Birmingham, Alabama. He assumed his duties at the local hospital on January 5.*

• • •

Dr. Luther A. Thomas, of Corning, was elected president of the Board of Directors of Corning Hospital on January 4. George D. Macbeth was elected first vice-president, Mrs. Alan W. Hawley, second vice-president, and Walter W. Oakley was re-elected secretary and treasurer.

The resignation of Mason B. Coger as a director was accepted, but no successor was elected.

The new board president deferred appointment of committees until a later meeting.*

• • •

The annual meeting of the medical staff of Veterans Memorial Hospital was held on January 2. The officers elected for the ensuing year were: Dr. J. Weiss, president; Dr. O. Roberts, vice-president; Dr. A. Ruggiero, secretary, and Dr. A. Augustine, treasurer.*

• • •

Appointment of Dr. Casper G. Burn, associate professor of pathology at the Long Island College of Medicine since 1938, as director of the laboratory at Kings County Hospital, and the receipt of a $5,000 gift to increase the laboratory facilities of the L. I. College of Medicine at the hospital, have been announced by Dr. Jean A. Curran, president of the college.

For ten years the Long Island College of Medicine has had a division at the Kings County Hospital staffed by its faculty members. Dr. Burn's appointment provides a further strengthening of the affiliation with the hospital. Under the new program the college is taking over four rooms for research and is installing laboratory and library facilities.

This expansion of the program at Kings County Hospital is concurrent with expansion of laboratory facilities at Hoagland Laboratory and Polhemus Memorial Clinic in the departments of medicine, anatomy, chemistry, and also the installation of a new radio-biological laboratory, for which an expenditure of $55,000 is being made. These projects are just a beginning in a long term development program outlined by the Board of Trustees. In the near future, Dr. Curran said, the college will need new buildings and further expansion of its teaching and research programs.*

• • •

Dr. Philip Freinberg, Hudson dentist, has been elected a member of the Board of Trustees of the Hudson City Hospital.*

• • •

The Lutheran Hospital Association of Brooklyn held its annual election in the latter part of December and chose the following officers: president, John G. Nelson; vice-president, William Muller; financial secretary, Otto C. Etterwendt; treasurer, August J. Mayer; chairman of the Board, Albert H. Legenhausen.

The following trustees were elected for a period of three years: Albert H. Legenhausen, John Krauss, William Messner, and Cord Steneck.

Eve Garnsey, R.N., is at present Acting Superintendent of the hospital.*

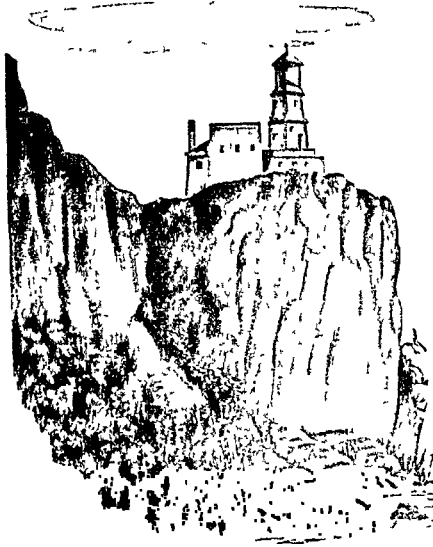
• • •

Dr. J. Spottiswood Taylor, who resigned as director of the laboratories of the Poughkeepsie Board of Health on December 31, is continuing as director of the laboratories at Vassar Hospital.*

• • •

At the annual meeting of the Greene County Memorial Hospital staff, Dr. T. Earl McQuade, of Coxsackie, was elected president, Dr. Ray Persons, of Cairo, vice-president, and Dr. George L. Branch, of Catskill, secretary.

Dr. Edwin Mulbury, of Windham, Dr. Alton B. Daley, of Athens, Dr. Kenneth F. Bott, of Greenville, and Dr. Mahlon H. Atkinson, of Catskill, are the other members of the board.*



Newsy Notes

The Hospital for Joint Diseases, New York City, is conducting a special study on the treatment of acute and chronic osteomyelitis patients with penicillin. Physicians are requested to refer such patients to the hospital by calling Lehigh 4-5500 and asking for the Admitting Office.

• • •

A medical staff meeting of the Alice Hyde Hospital, Malone, and members of the hospital executive board was held December 19 at the Elks Club. Capt. Chester Rutkowski, recently returned from

[Continued on page 432]

"THE HOUSE BUILT UPON A ROCK"

THE PARABLE of the house built upon a rock and the house built upon the sand has stressed for all time the universal importance of a solid foundation. In the human body, among the important building-stones of that solid foundation are calcium, phosphorus and vitamin D.

Today many of the foods which contain these elements are restricted by war-time shortages. Even in normal times the dietary idiosyncrasies and phobias of many patients may prevent their obtaining adequate intake of these essential factors from food.

Squibb Dicalcium Phosphate Compound with Viosterol is a convenient, economical and palatable form in which to prescribe these necessary nutritive elements. It is available both in capsules and in candy-like wintergreen-flavored wafers.

One wafer supplies your patient with 2 6 gr. (168 mg) of calcium, 1.6 gr. (103 mg.) of phosphorus and not less than 660 U.S.P. units of vitamin D. The vitamin D content—equivalent to that in more than two teaspoons of U.S.P. cod liver oil — is adequate to assure utilization of the minerals. Two capsules are equal in calcium, phosphorus and vitamin D content to one wafer. The capsules are usually preferred by women during pregnancy.

Recommended dosage: 3 to 6 wafers daily, or double that number of capsules.

E. R. SQUIBB & SONS

Manufacturing Chemists to the Medical Profession since 1858

duty with the Army Medical Corps in France, was a guest at a dinner on this occasion.

Dr. F. F. Finney presided at the business meeting which followed the dinner.*

• • •

Acting to relieve a serious shortage of night ambulance drivers at the Troy and Leonard Hospitals, officers of the Troy Post, 27th Division Veterans Association, on December 19 announced plans by which members of their organization would be made available for ambulance service at the institutions.

A complete schedule and list of volunteers to relieve the shortage of drivers at the two city hospitals was drawn up at the January meeting of the post, Clyde W. Heer, commander, announced.

The Troy Post, which has answered calls for volunteer help at the Rensselaer County Troy City War Price and Rationing Board, will make available for the driving of the ambulances a number of its members living in the vicinity of the hospitals.*

• • •

Purchase of a large instrument table for use in Corning Hospital operating room was voted at the executive meeting of the Woman's Community Club, Corning, which preceded the program on January 4.*

• • •

The annual meeting of the Benedict Memorial Hospital Association was held at the Hospital in Ballston Spa on January 8 at 8 P.M. Reports were given. Three directors were elected to replace Mr. Rooney, Mrs. Andrews, and Mrs. Dorman, whose terms of office had expired.*

• • •

Utica hospitals are holding open house for young women of the region who are contemplating nursing careers. The series started January 11 at St. Luke's Hospital; at Utica Memorial the program took place on January 12; on February 12 at Faxton; at St. Elizabeth, February 22; and at Utica State on April 4. The afternoons consist of a tour of the hospital, an address by the principal of the school of nursing, and a tea.*

• • •

Following the success of Sydenham Hospital as an interracial voluntary hospital, three other institutions in New York City have added colored physicians to their staffs, the first annual statement of the trustees of the hospital to the organization committee said on January 3.

The first meeting of the reorganized board of trustees of the hospital was held on December 20, 1943, at which time it voted to establish an interracial voluntary hospital.

• • •

The first volunteer corps of trained nurses arrived at Halloran Hospital on Staten Island on January 20 to put in a full eight-hour day helping to care for the war-wounded at the request of the Army. They were assigned to general duty on the wards, giving much-needed assistance to a staff which is overworked because of the shortage in the Army Nurse Corps.

Under arrangements made at a meeting of the New York Chapter of the Red Cross, the nurses will wear their own hospital uniforms and the cap of their nursing school; or, in the case of public-health nurses, they will wear the uniform of their organization, to distinguish them from members of the Army Nurse Corps.

• • •

Dale's Sanitarium, in Saugerties, operated and supervised by Mrs. Ruth Dale, R.N., has been given a hospital rating by the State Department of Health.

• • •

The formation of a New York Advisory Board for the National Jewish Hospital at Denver, the first tuberculosis institution in America to provide free medical and surgical care to needy men, women, and children on a national, nonsectarian basis, has been announced by Brig. Gen. Julius Ochs Adler, who is vice-chairman and in charge in this area of the hospital's activities.

The advisory board here will be headed by John Block, president of Kirby, Block & Co., and serving with him will be prominent business executives who will direct the New York program.

"Approximately one-third of the hospital's patients, who receive medical and surgical care for all types of tuberculosis, come from New York City and vicinity," General Adler said. "Wartime strain on men and women in the armed services, as well as on workers in war industries and the civilian population in general, will be reflected, undoubtedly, in an increased number of tuberculosis victims."

Members of the board in addition to Mr. Block and General Adler, are Sanford S. Agate, Seymour R. Askin, Carl Byoir, Herman Chopak, Emil Friedlander, Leonard Ginsberg, Morris W. Haft, Samuel Hausman, Lothair Kohnstamm, Benjamin Lazrus, L. M. Rabinowitz, A. J. Schuel, and Maj. Paul Felix M. Warburg.

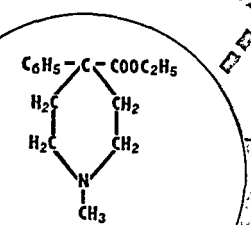
• • •

In letters mailed the week of January 1, Carll Tucker, president, and Theodore C. Slosson, treasurer of the Northern Westchester Hospital, are making the annual appeal for financial support for that institution, which serves all sections of Northern Westchester and points south.*

• • •

Legislation which would transfer jurisdiction of Fort Hamilton from the War Department to the Veterans Administration was proposed in January by Representative Donald L. O'Toole, Democrat, of New York.

Terming the measure a first step in an effort to bring a veterans hospital to Brooklyn, site of the fort, Mr. O'Toole declared that the reservation is "obsolete" as a military post in peacetime. "Fort Hamilton," he said, "will serve the country and community far better as a veterans hospital than it will as a military post."*



• • •

An inclusive-rate program, under which hospital patients pay a uniform daily price and receive the use of hospital facilities normally billed as extras, was put into effect last July at New York Hospital,

525 East 68th Street, and on January 20 was pronounced a success.

Dr. John B. Pastore, assistant superintendent of New York Hospital, said that a recent survey had disclosed beneficial results of the program, for both the hospital and the patient.

The program was devised thirteen years ago by the University Hospitals in Cleveland, and the Evanston Hospital in Illinois. Although the Jewish Hospital of Brooklyn inaugurated the program several years ago, New York Hospital is the first in Manhattan to adopt the plan for all patients. Three other city hospitals are offering the inclusive rate for ward or semiprivate patients, and others are expected to follow.*

. . .

The annual meeting of Rockaway Beach Hospital and Dispensary was held on January 25, it has been announced by William H. Reynolds, president of the hospital's board of directors. At the meeting reports were given concerning the condition of the hospital and its progress for the past year.

This year special interest was taken by many people in the report of the progress of the building fund campaign which the hospital started last year in the hope of being in a position to commence work on a new plant as a postwar project.

Directors were elected at the meeting to fill vacancies caused by the expiration of the terms of several members of the board. The board of directors met following the annual meeting to select the governing body's officers for 1945.

. . .

The enthusiasm of one hundred men who attended a dinner in the Veterans Memorial Building, Albion, on December 15, and the expressions of whole-hearted cooperation voiced by many of them in connection with the campaign to provide a new hospital in Albion give promise that the minimum of $125,000 sought will be forthcoming from the people in central and eastern Orleans County, who will benefit from the new and much-needed institution. Decision of the meeting was that the case will be carried to these same people of the entire county east of Medina.

Edward Archbald accepted the general chairmanship of the campaign and Leon C. Grinnell and Mervil LaRowe agreed to act as cochairman of the Special Gifts committee.

. . .

Doctors on the courtesy staff of Ellis Hospital, Schenectady, have been advised of their appointment by the board of managers for 1945 and of several changes in rules and regulations which have been recommended by the hospital's attending staff.

The changes which it is necessary to enforce have been planned for the good of the hospital's service to the community, according to Chester H. Lang, president of the board of managers.

In the future because of the shortage of trained personnel, all patients entering the hospital for an operation must be admitted between 3 P.M. and 5 P.M., the day prior to the operation. Only in emergency cases will an exception be granted to this ruling.

The hospital also is asking doctors to notify head nurses on the day before the discharge of a patient from the hospital whenever possible. Patients will be discharged before noon of the following day in order to prepare beds for incoming patients.

In connection with this ruling it was noted that the hospital now is handling more medical cases than ever before in its history.

The medical staff also has ruled that no patient with epidemic type of meningitis, primary syphilis, or acute gonorrhea will be admitted during the present emergency; all doctors must comply with the ruling that patients must have a tentative admission diagnosis before entering the hospital, and no patient shall be sent to the hospital without arrangements being made with the admission office, emergency cases excepted.*

. . .

The late Mrs. Eleanor G. Lansing, former president of the Little Falls Hospital Association, has bequeathed to the Hospital $10,000 outright, to be placed in a fund known as the "Eleanor G. Lansing Fund," and one half of the residuary estate.*

. . .

Faced with a demand far exceeding its present facilities, New Rochelle Hospital through its board of governors announced on December 20 a $750,000 emergency building campaign.

The funds would pay for the immediate construction of a seven-story addition to the Central Unit of the hospital and for the building of a new South Wing to replace the present outmoded and inadequate structure.

The campaign got under way in December with Samuel F. McDonald, of Mamaroneck, as chairman. He is head of the hospital board's ways and means committee.

The seven-story addition is to be erected directly over the one-story administration offices inside the main entrance facing Burling Lane. Hospital officials expect to be able to start construction of this addition in March and conclude it within nine months.

The probable cost of this addition will be $250,000. Application for release of the necessary materials is being made at once, hospital authorities said, and no difficulty is expected in obtaining priorities because of the urgency of the situation.

The second part of the $750,000 building program will replace a wing which was erected in 1908 and is now obsolete. The board of governors revealed that it had found that the building could not be reconstructed to accommodate modern requirements.

Construction of this new south wing will be undertaken as soon as plans can be drawn and steel and other building materials are available. The probable cost is $500,000.*

. . .

A community bed for the use of indigent patients will be established at the Nyack Hospital as a memorial to the late Francis A. Glass when present plans materialize. The movement was initiated by Mesdames Henry Poor, Maxwell Anderson, and Milton Caniff, found willing acceptance, and was immediately sponsored by the patients and friends of the late doctor in the towns of Haverstraw, Stony Point, Clarkstown, and elsewhere, and will be in appreciation of his hard work and sacrifices in behalf of his fellowmen. A list of contributors to the fund will be placed on file at the Nyack Hospital.*

business and professional men in the staff-depleted hospitals of Westchester County was spotlighted when the White Plains Hospital announced award of a citation to Harry L. Johnson, of White Plains, for his completion of 1,000 hours of menial work as a volunteer orderly in the institution.

The citation, presented by the hospital's medical staff and volunteer orderly corps, was described by William G. Illiner, hospital administrator, as a "warm-hearted expression of deep gratitude" for the labor of Mr. Johnson in helping to maintain in wartime the standards of a community hospital.

Bankers, clergymen, engineers, lawyers, judges, salesmen, teachers, writers, and business executives —80 per cent of them commuters—are among the volunteers who serve as orderlies at the White Plains Hospital in spare time now that the usual staff of ten paid orderlies has fallen to two.

• • •

Leaving behind the stages of deliberation and planning, supporters of the new Kenmore Mercy Hospital launched the active phase of the project in December by seeking financial support from more than three score industrial plants in the area to be served by the institution, it was announced on December 16.

The campaign, designed to raise at least $250,000 of the $1,250,000 needed to erect the seven-story structure, will be in charge of Albert A. McMullen, president of the State Bank of Kenmore, and Attorney Albert T. O'Neill, vice-president of the Buffalo Niagara Electric Corp.

WE STILL NEED A BOOK

A letter was read to the Executive Committee of the Council at its August meeting asking for information. A junior medical student asked his father why more effort is not being made to place information before groups of medical students. He complained that these students get plenty of propaganda favorable to state medicine, bureaucratic practice, group practice, salaried positions, but none about the ideals and privileges of private practice. The ethics and economies of medical life and practice are learned only incidentally, and haphazardly.

The book we suggested several months ago has attracted the attention of others and efforts are being made to sound the possibilities. We admit the writing of such a book is a labor of no small proportions, but we submit that that work is seriously needed, and will be forthcoming. This query from a junior medical student shows one phase of the need. It also shows a defect in our medical courses that has been apparent for decades. Many times it has been suggested that some well-informed private practitioner of medicine be chosen to give a course of lectures on problems of medical practice, relations to patients, finance, and medical ideals, at our medical schools, elective, if thought best, but one that all the students would be invited to attend. Sporadic attempts have been made but not continued.

This *book* could be so written that it would serve as a text in such a course and would be available for reference to inquiring students in medical and sociologic fields, who are asking for the medical side of socialized or state medicine.

Yes, we need a book—NOW!—*Editorial in the Journal of the Michigan State Medical Society, Oct., 1944*

NAVY ESTABLISHES FILARIASIS REGISTRY

A filariasis registry was recently established by the Bureau of Medicine and Surgery at Marine Barracks, Klamath Falls, Oregon, which is the reconditioning center for Marines returned to the United States from the Pacific because of malaria or filariasis. The registry is to make and keep a record in a central place of all Navy and Marine Corps personnel having a diagnosis of filariasis. Establishment of this centralized record-keeping system will facilitate keeping filariasis patients under surveillance as long as they are on active duty. The information obtained will also make it easier to evaluate the extent of the problem presented by the disease and make possible an adequate follow-up system for effective handling of patients. All naval stations in the United States have been directed to examine health records so that if an entry of filariasis has been made for any individual the data can be forwarded promptly to Klamath Falls.—*J.A.M.A., Dec. 2, 1944*

Woman's Auxiliary

To the Medical Society of the State of New York

County News

Orange County. At the regular meeting of the Women's Auxiliary to the Medical Society of the County of Orange, held in Montgomery on December 11, sixteen members were present. Because the county territory is very spread out and because of the gas situation these meetings are held at the same time as those of the Medical Society. After a delicious steak dinner the meeting was called to order and presided over by the president, Mrs. Harry L. Chant. There are sixty-seven paid-up members and seven prospective members.

Plans for an open meeting to be held in April were discussed, after which Mrs. Albert Green gave several delightful readings.

Schenectady County. The auxiliary to the Schenectady County Medical Society held a tea on December 28, 1944, at the home of Mrs. Beverly Vosburgh, of Schenectady. The members of the executive board were hostesses and past presidents of the group poured.

Attending were Mrs. Arthur H. Congdon, Mrs. Alfred Grussner, Mrs. Nelson H. Rust, Mrs. Herman W. Galster, Mrs. R. J. McManus, Mrs. F. Leslie Sullivan, Mrs. D. H. R. Lester, Mrs. Albert Greene, Mrs. Thomas Adinolfi, Mrs. James Blake, Mrs. Arnoldo Samorini, Mrs. Roland Faulkner, Mrs. Gomer Richards, Mrs. George von Borstel, Mrs. Joseph Cornell, Mrs. R. L. MacDowell, Mrs. Milton F. Gilstein, Mrs. Arthur Q. Penta, Mrs. T. Watson Smith, Mrs. William J. Burns, Mrs. John H. Kalteux, Mrs. Victor Henlein, Mrs. L. K. Milton, Mrs. William Jameson, Mrs. Charles F. Rourke, Mrs. D. Glen Smith, Mrs. C. W. Woodall, Mrs. William Mallia, Mrs. David Vrooman, Mrs. Herbert Monheimer, Mrs. James Smith, and Mrs. Clarence W. Jones, of Stamford, Conn.

PREGNANCY AND TUBERCULOSIS

Treatment of the pregnant woman with tuberculosis by the most modern methods of combating the disease together with equally modern prenatal care apparently offers her as good a chance for recovery from her tuberculosis as though pregnancy did not exist.—*Tr. Nat. Tuberc. A., 1941*

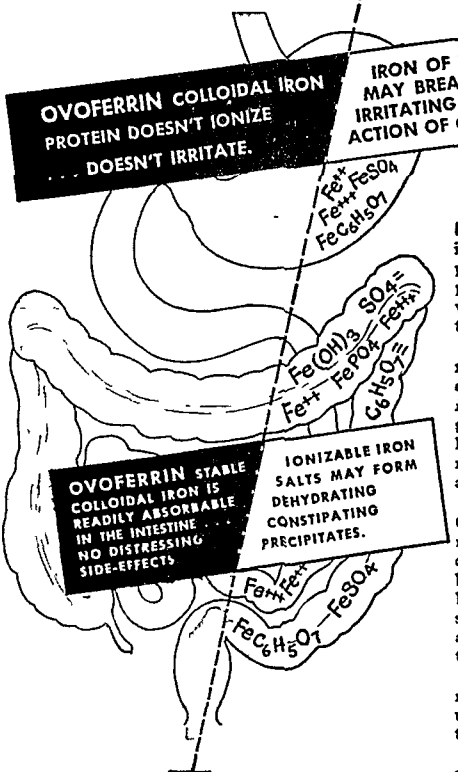
PENICILLIN IN RHEUMATIC FEVER

Penicillin appears to have no value in the treatment of acute rheumatic fever

This has been reported by two separate groups of investigators in separate reports in the *Journal of the American Medical Association* for September 30.

in **HYPERTENSION**

Answer it with **HEPVISC**



High blood pressure brought down to safer levels by gradual, prolonged action of HEPVISC. Also relieves headaches and dizziness.

DOSE: 1-2 tablets t.i.d., after meals.
Sample and formula on request.

ANGLO-FRENCH LABORATORIES, Inc. • 75 VARICK STREET, NEW YORK 13, N. Y.

COLLOIDAL IRON vs / Ionizable Iron

In hypochromic anemia when iron therapy is indicated Ovoferrin provides colloidal, assimilable iron protein that is readily absorbed without distressing side-effects for the patient.

No dehydration, no constipation, no irritation from ionizable salt precipitates because *Ovoferrin doesn't ionize.* Ovoferrin iron enters the gastro-intestinal tract as a fully hydrated oxide in colloid state . . . readily absorbable . . . promptly assimilated.

Today especially physicians find Ovoferrin effective in combating nutritional anemias of infants, children and adults. In chlorosis, in debility states, in anemia following blood loss, after gastro-intestinal surgery and in anemia frequently associated with pregnancy and lactation.

Pleasant to take. Ovoferrin has no disagreeable taste or odor to upset the patient. Doesn't stain the teeth.

Ovoferrin is available at drug-stores in 11 oz. bottles. Dosage: One tablespoonful in water at mealtime and at bedtime.

No disagreeable taste. Does not stain teeth.

OVOFERRIN *COLLOIDAL ASSIMILABLE IRON*

MADE BY A. C. BARNES CO., NEW BRUNSWICK, N. J.

REVIEWED

The Compleat Pediatrician. By Wilburt C. Davison, M.D. Fourth edition. Octavo of 256 pages. Durham, N.C., Duke University Press, 1943. Cloth, $3.75.

This fourth edition is almost a "must" in the libraries of pediatricians and those handling infants and children medically. It is difficult to understand how so much valuable material has been assembled in such orderly fashion in 256 pages. So well is it integrated that to point out the merits of any one chapter would be the height of folly. One would have to know the meticulous spirit of the author to understand the exactness of its pages. Other words than these would be superfluous.

THURMAN B. GIVAN

Virus Diseases in Man, Animal and Plant. By Gustav Seiffert. Translated by Marion Lee Taylor. Octavo of 332 pages, illustrated. New York, Philosophical Library, Inc., 1944. Cloth, $5.00.

This volume, according to the author, is "A survey and reports covering the major research work done during the last decade." The book is divided into three parts. It consists of a general discussion of the virus problem, a special part treating with the various diseases of plant, animal, and man, and chapters on methods of virus investigation.

Although recently edited, the book is actually not up to date. The important work done since 1938

TOLL OF WAR ON CHILDREN

Swiss physicians report that diet deficiencies in France in calories, protein, minerals, and vitamins are producing deficiency diseases, delaying growth, and greatly lowering resistance to acute and chronic infections in French children. Tuberculosis, rickets, scurvy, and dermatitis are rapidly increasing and living conditi[illegible] ous effect on [illegible] cial attitudes [illegible] are reports of alarming increases in visual and hearing defects. In all these countries hunger is combined with suffering from cold, due to lack of fuel for homes, and to lack of clothing and shoes.—*Martha Koehen, Ph.D., Ohio State M. J., Sept., 1944*

RELIEVE TEETHING PAINS in Babies with CO-NIB

Mothers appreciate your prescription of CO-NIB because its quick-acting ingredients effectively soothe teething pains.

[Continued from page 440]

is completely omitted. In addition, the translation is unbelievably poor and the scientific terms are misused. However, there are parts of the book that are well treated, though not very exhaustively. The best that one may state for this volume in its present form is that it may help complete a library of virus surveys. M. LEDERER

Fundamentals of Psychiatry. By Edward A. Strecker, M.D. Second edition. Duodecimo of 219 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1943. Cloth, $3.00.

Present events have emphasized the importance of psychiatric knowledge to medical officers, industrial physicians, and to doctors in private practice in order to enable them properly to perform their duties and understand their patients. World War I has cost this country one billion dollars for the care of psychiatric casualties. This war is longer, bigger, and threatens us with an expense in this regard that staggers the imagination. This book, an outgrowth of the teaching experience of one of the leading specialists in his field, comes at an opportune time. Although concise, it covers the more common conditions, affords an insight into mental mechanisms and psychopathology, discusses more recent advances such as the "drastic" therapies, and has useful chapters on the "war neurosis" and psychiatric nursing. It is one of the best brief books on the subject that has appeared and is to be highly recommended to those who require an introduction and a workable picture of the medicine of the mind.

MATTHEW BRODY

Surgical Disorders of the Chest. Diagnosis and Treatment. By Maj. J. K. Donaldson, M.D., (MC), AUS. Octavo of 364 pages, illustrated. Philadelphia, Lea & Febiger, 1944. Cloth, $6.50.

This book was written expressly for the physician and surgeon who occasionally encounter a thoracic surgical problem. Since this book was chiefly designed for such readers, it would have been profitable to indicate the expected results of the surgical procedures recommended in the various diseases. This book contains a wealth of information, presented succinctly, and is highly recommended as a worthy addition to the physician's and general surgeon's library.

LEW A. HOCHBERG

Textbook of Gynecology. By Emil Novak, M.D. Second edition. Octavo of 708 pages, illustrated. Baltimore, Williams & Wilkins Co., 1944. Cloth, $8.00.

The second edition of Novak's *Textbook of Gynecology* approaches the subject matter in a fashion similar to that of his first edition. Diagnosis and treatment of the various gynecologic problems are thoroughly discussed. On the other hand, surgical procedures are merely mentioned and as a result students and general practitioners are not required to delve through a maze of valueless material.

Two new chapters have been added. One is devoted to the embryology of the female generative tract, and the other covers urologic problems confronting the gynecologist. Pathologic and endocrinologic problems in the field of gynecology are fully discussed. The text is profusely illustrated with excellent black-and-white and colored photographs.

This book should prove to be of interest and value to the student, the general practitioner, and the specialist and will be more popular than the preceding edition. M. GLASS

Medical Care of the Discharged Hospital Patient. By Frode Jensen, M.D., H. G. Weiskotten, M.D., and Margaret A. Thomas. Octavo of 94 pages. New York, Commonwealth Fund, 1944. Cloth, $1.00.

The authors certainly struck a familiar note when, after a study of the question, they state "how unsatisfactory was the medical care of ward patients after discharge from the hospital." All hospital men will agree with this; and they often are conscious of the waste of time, money, and effort required for the solution of a medical problem because the follow-up of the patient was either entirely absent or grossly inadequate.

This small volume offers many useful suggestions and methods as to how this inadequacy can best be met. The book is written in a clear and compact style, has an extensive bibliography, and to those interested in the subject it is indispensable.

S. R. BLATTEIS

Clinical Lectures on the Gallbladder and Bile Ducts. By Samuel Weiss, M.D. Octavo of 504 pages, illustrated. Chicago, Year Book Publishers, Inc., 1944. Cloth, $5.50.

This book consists of a series of thirty lectures and is a worth-while contribution to the literature on biliary tract diseases. The early lectures on anatomy, physiology, history-taking, and physical examination are clear and concise. A lecture on radiology by Dr. E. E. Smith is excellent. Duodenal drainage is perhaps overemphasized. The lectures on the diseases of the tract are very instructive and abound in references to the literature. Jaundice is well presented and some valuable charts are presented. The liver-function tests are briefly but clearly described and evaluated. A lecture on preoperative and postoperative care is very important. The book is well printed and has a valuable index. On the whole the book can be recommended both for students and practitioners.

A. F. R. ANDRESEN

Heart Disease. By Paul Dudley White, M.D Third edition. Duodecimo of 1,025 pages, illustrated. New York, Macmillan Co., 1944. Cloth, $9.00.

The third edition of this excellent book is welcome. In arrangement it is similar to the previous editions, but some of the references which were omitted from the last edition have been restored, thus enhancing its value. Some parts have been rewritten, and new material has been added. The whole subject is admirably presented and on debatable issues the author has stated his opinion in a conservative way based on the facts which exist. Throughout the book each phase is considered in the light of the author's large clinical experience, due recognition being given to the contributions of others. The historic references add greatly to the interest and the extensive references direct the reader to the important papers so that if more detail is desired than can be included in a textbook it can be easily obtained. In the reviewer's opinion this is the best book on cardiology at present and should be in the library not only of those who are specially interested in heart disease but also of medical students and physicians whose interests are more general. PSYCHIATRIC SERVICE FOR THE RETURNED VETERAN

At the meeting of the American Psychiatric Association last spring, it was announced that the objectionable label "psychoneurotic" had been dropped from the records of selectees rejected for nervous and mental conditions and replaced by the phrase "not suited for military service." This is a sensible designation, much more accurately describing the facts, since many individuals unfitted for the intense emotional hazards of modern warfare will prove successful, and often superior, members of a civilian community.

The fundamental fact remains, however, that, according to Col. L. G. Rowntree of Selective Service, between 30 and 40 per cent of rejections and discharges have been related to mental and nervous status and that the total number of persons of this type in the rejected and discharged groups combined will exceed two million.

So far as discharges are concerned, the Veteran's Bureau will no doubt provide institutional care for those in need of such treatment. The great majority of both rejected and discharged groups will, however, need outpatient care alone, or outpatient care subsequent to hospitalization. The urgent question before us today is how and where this outpatient care shall be provided; and there are three major alternatives. Shall mental hygiene clinic provision be made as a special service for discharged soldiers under the direction of Veteran's Bureau hospitals? Shall it be made through community mental hygiene clinics serving all persons in need of this special type of care? Or shall it be developed as an expansion of the outpatient service of general hospitals?

It seems reasonably clear that the first of these three alternatives is least desirable. The development of new outpatient clinics under the Veteran's Bureau would involve serious duplication in a field where concentration of effort is essential. Furthermore, the treatment of the discharged soldier in such clinics would tend to label him as a special type of military psychoneurotic whereas he is essentially the same kind of individual as the rejectee for mental and emotional causes and as the ordinary civilian with similar difficulties. The strain which has accentuated his problem is different; but the task of adjustment to civilian life is the same.

On the question whether we should build increased mental hygiene service on independent mental hygiene clinics or on the outpatient services of general hospitals, Dr. J. M. Cunningham, of the Connecticut State Department of Health, has presented a challenging argument. He points out that in addition to the men who have received various psychiatric labels at the hands of induction boards or service doctors, there is another large group in which emotional and physical defects are closely interrelated in what are now classed as psychosomatic disorders. Dr. Cunningham believes that the "integration of psychiatry and medicine may be expected to be the next great development in the application of psychiatric knowledge." Therefore, all "psychiatric service for adults should be organized as a part of the general hospital and it should be integrated with the other medical services for both in- and outpatients." He suggests that there should be appropriations to subsidize psychiatric diagnosis and treatment in the general hospital for both inpatient and outpatient work; that this service should be on a full-time paid basis utilizing psychiatrists, psychologists, and psychiatric social workers; and that such services should provide for veterans along with all other adult members of the community.—*Ed., Am. J. Pub. Health, Dec., 1944*

WHEN MILK BECOMES "FORBIDDEN FOOD"

MULL-SOY FOR EQUIVALENT NUTRITION

While the manifestations of milk allergy or intolerance are most often seen in infants they may be present at any age. And when successful treatment demands complete elimination of milk from the diet *replacement by food approximately equivalent in nutritional elements* becomes imperative.

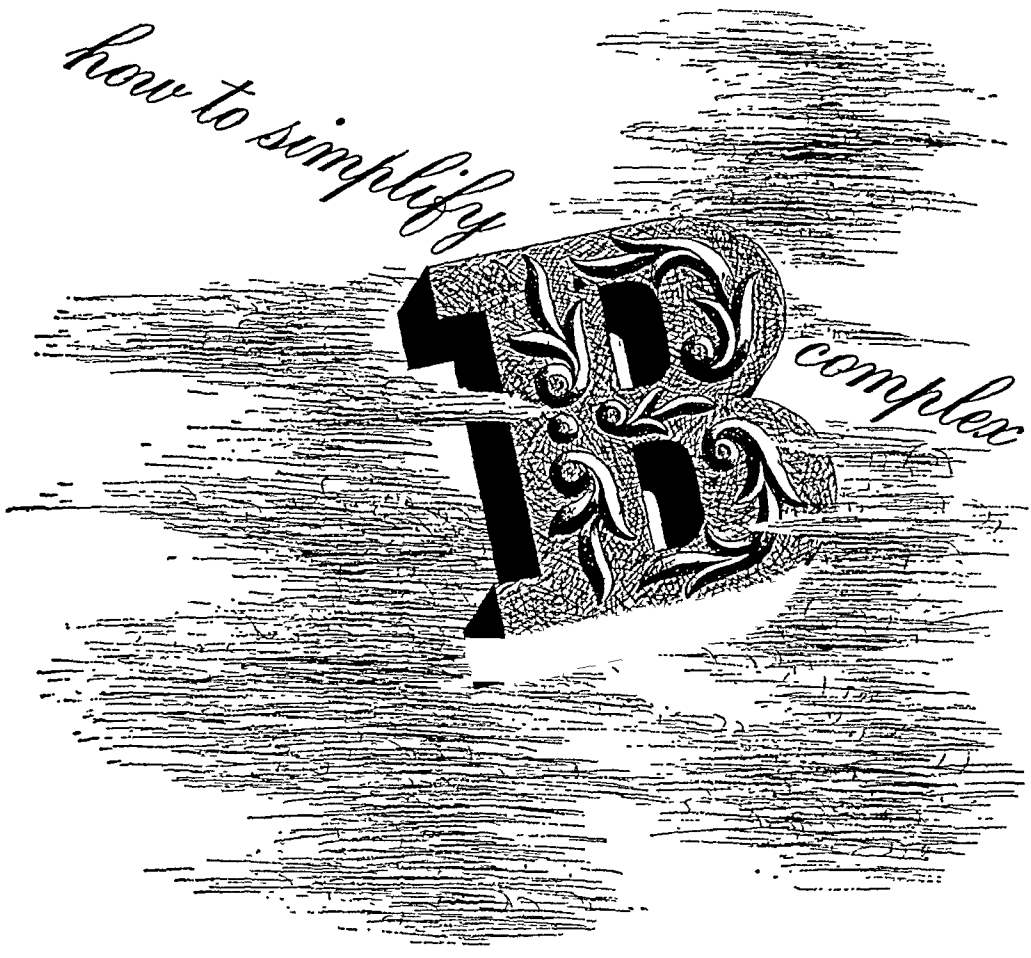
MULL SOY is an effective hypoallergenic substitute for cow's milk — a concentrated emulsified liquid soy bean food which closely approximates cow's milk in protein fat carbohydrate and mineral content. It is palatable well tolerated easy to digest and easy to prepare. Infants particularly relish MULL SOY — and thrive on it!

Copies of "TASTY RECIPES FOR MULL SOY IN MILK FREE DIETS" are available for distribution to milk allergic patients. Write

BORDEN PRESCRIPTION PRODUCTS DIV. 350 MADISON AVE. NEW YORK

COMPARATIVE COMPOSITION

1 Part Mull Soy 1 Part Water		Average Whole Cow's Milk
3.1%	Protein	3.3%
4.0%	Fat	3.8%
4.5%	Carbohydrate.	4.9%
1.0%	Total Minerals	0.7%
87.2%	Water	87.3%



Each provides 20 calories per fluid ounce

MULL-SOY

Hypoallergenic Soy Bean Food

MULL-SOY is a liquid emulsified food prepared from water soy bean flour soy bean oil, dextrose sucrose calcium phosphate calcium carbonate salt and soy bean lecithin homogenized and sterilized. Available in 15½ fl. oz. cans at all drug stores

Habit is half the battle in successful vitamin B medication. To establish treatment firmly in the patient's daily routine, the prescription must be, first of all, pleasant to taste and easy to take.

That's why physicians find *Maltine B* an excellent choice. Completely free of the usual yeasty or musty flavor, it's a favorite with young and old alike.

Only two teaspoonfuls of *Maltine B* per day supply protective quantities of B Complex vitamins for adults, and one teaspoonful furnishes children's requirements. Supplied in prescription size of 8 fluid ounces, sufficient for a month or more of prophylactic use.

For LOCAL ANESTHESIA

PROCAINE HYDROCHLORIDE

Brewer

Current literature continues to report on the use of Procaine Hydrochloride as a local anesthetic.

In the removal of moles, ordinary seborrheica and senile keratoses from the body, the area is first anesthetized with procaine hydrochloride (A. Benson Cannon; *N. Y. S. J. M.*; Vol. 40, No. 21, p. 1569).

As less toxic than most cocaine substitutes it is especially safe for the production of spinal anesthesia. It's continued use for infiltration anesthesia, conduction anesthesia, for topical use in ophthalmology, in rhino-laryngology and for urethral anesthesia finds it still indispensable to the doctor.

Supplied in 2 per cent solution
in ampules of 2 cc. and 30 cc.

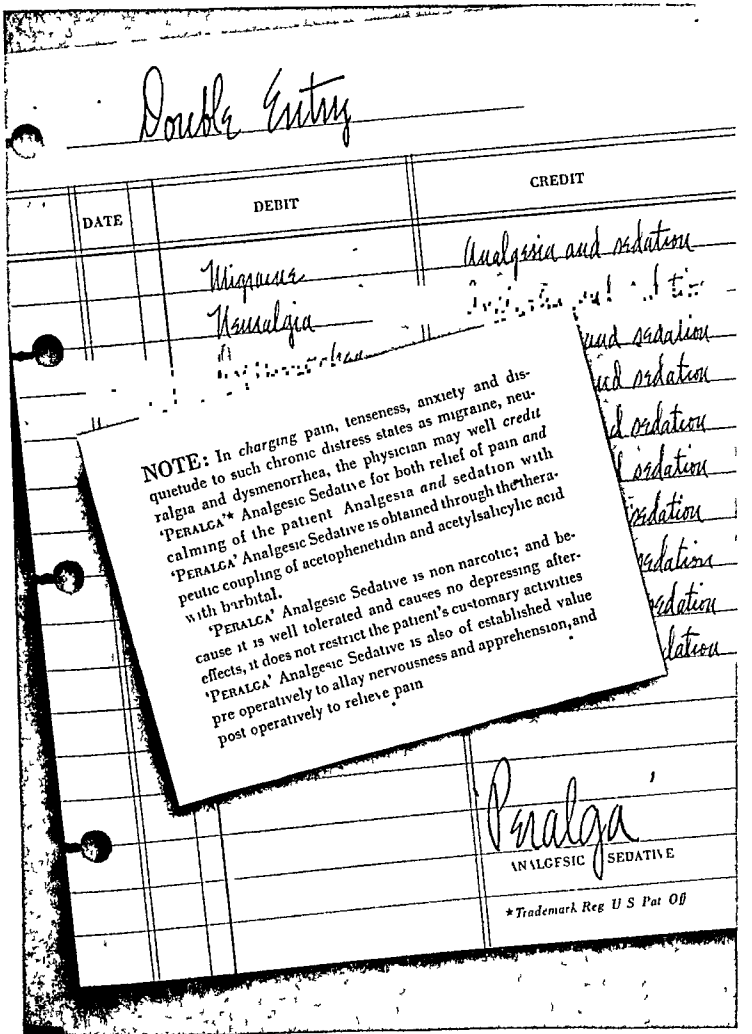
IN DISORDERS OF GASTRIC FUNCTION

Gastron
REG. U.S. PAT. OFF.



GASTRON is an original extract of the organic and inorganic constituents of the entire mucosa of the hog-stomach, including the pylorus. The acidified and aromatized extract is incorporated in an aqueous - glycerin menstruum which preserves the enzymatic activity. The preparation contains no alcohol. It is accurately standardized by assay.

GASTRON is indicated as replacement therapy in atrophic gastritis, and as an aid in the treatment of chronic gastritis. It is of value as adjunctive treatment in the anemias, and in certain gastric deficiencies associated with convalescence and old age. It is worthy of trial in the nausea and vomiting of pregnancy.

GASTRON *WITH IRON* also is available for prescription use

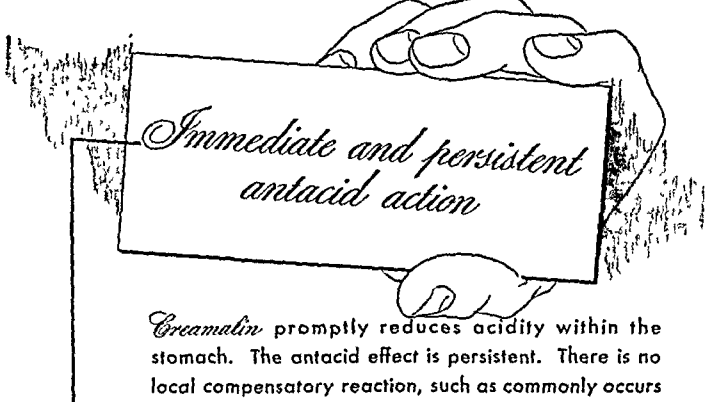
FOOTWEAR



for **CORRECTIVE TREATMENTS**

No animal laboratory tests can supply information as a guide to the proper choice of therapeutic footwear. Only the hard-earned experience gained over a generation of fitting shoes to all conditions of feet, and learning from the experience of individuals in all age groups who have not been fitted properly before, can provide the essential knowledge adequate for manufacturing and fitting helpful shoes.

Add to this the recommendations of specialists in medicine and you have a dependable source for beneficial footwear that supplements your treatments of any member of the family.

Convenient sources:

Immediate and persistent antacid action

Creamalin promptly reduces acidity within the stomach. The antacid effect is persistent. There is no local compensatory reaction, such as commonly occurs with alkalies, and hence no belated oversecretion of hydrochloric acid. Moreover, there is no risk of producing alkalosis.

Creamalin promptly relieves pain and heartburn associated with gastric hyperacidity

Creamalin often induces healing of peptic ulcer when employed with an ulcer regimen.

PENICILLIN SCHENLEY

Product of a common mold... but most uncommon care

The mold which produces penicillin is a mold of a fairly *common* variety, occurring freely in nature. But the production of penicillin for the medical profession depends upon precautions to insure sterility which are *most uncommon.*

One of the most important requirements of the finished penicillin is freedom from pyrogens. Each manufactured lot of PENICILLIN Schenley is tested (as illustrated above) to insure utmost pyrogen-freedom. Such measures of uncommon care will continue to assure the greatest degree of productivity . . . the highest degree of pyrogen-freedom . . . for PENICILLIN Schenley.

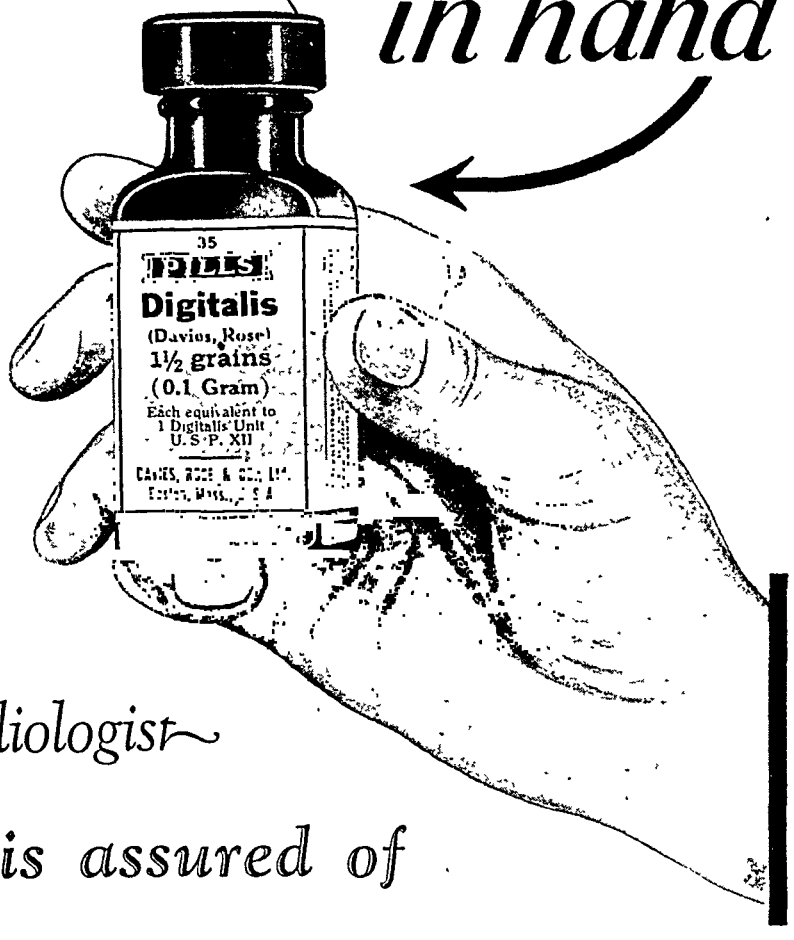
Producers of PENICILLIN SCHENLEY • Executive Offices: 350 Fifth Avenue, N.Y.C.

Post-Surgical Starvation

with its wastage of body tissues, especially tissue and plasma protein, "begins almost at once after protein is omitted from the diet." Hence it is recommended* that meat and other protein foods be added to the diet as soon as possible after surgery. Meat is not only rich in protein, but its protein is of highest quality, able to meet every protein need.

The Seal of Acceptance denotes that the nutritional statements made in this advertisement are acceptable to the Council on Foods and Nutrition of the American Medical Association.



*"Surgeons are accustomed to attribute most of the postoperative weakness or asthenia to the operative procedure without realizing that much of it may actually be due to starvation, particularly deprivation of protein . . . the fall in plasma albumin begins with the very onset of a protein deficient diet . . . Solid food, as eggs and meat, should be added as soon as possible. Most postoperative patients can eat food much earlier than they are usually permitted to." Elman, R.: Acute Starvation Following Operation or Injury: With Special Reference to Caloric and Protein Needs, Ann. Surg. 120:350-361 (Sept.) 1944.

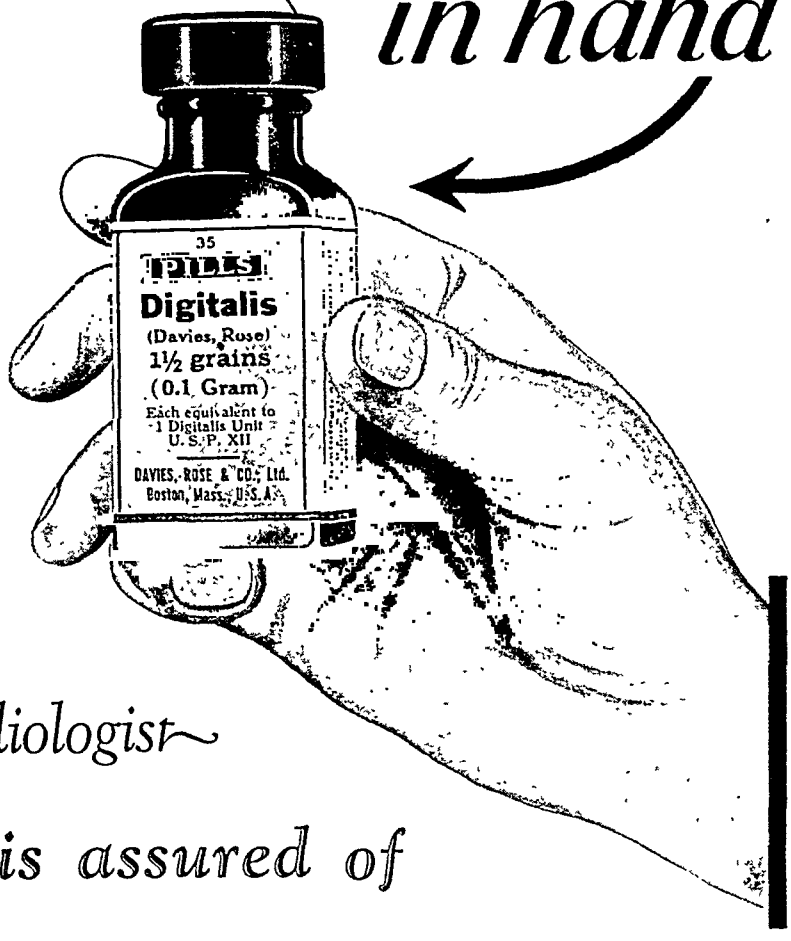
BELBARB

AN *Excellent* SEDATIVE *and* HYPNOTIC

The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg, Arch. f. exp. P. & P. CLX, 276) renders possible attainment of desired effects with relatively small doses, thus avoiding "hang over" and other unpleasant side-actions. In contrast to galenical preparations of belladonna, such as the tincture, Belbarb *has always the same proportion of the alkaloids.*



Indications: Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

Formula: Each tablet contains ¼ grain phenobarbital and the three chief alkaloids, equivalent approximately to 8 minims of tincture of belladonna.

Belbarb No. 2 has the same alkaloidal content but ½ grain phenobarbital per tablet.

SUPPLEMENT THE DIET WITH ESSENTIAL VITAMINS

Puretest Plenamins—A, D, B_1, C, E, G (B_2), B_6, Niacinamide, Calcium Pantothenate with Liver Concentrate and Iron Sulfate—are tested, checked and rechecked in the United Drug Company's Department of Research and Control, one of America's finest and most modern pharmaceutical laboratories.

Puretest Plenamins are economically packaged in amber and black capsules, and are available in quantities of 72, 144 and 288 to the box One amber and one black capsule supply the following essential vitamins:

Vitamin A..... ....5,000 U S.P. Units
Vitamin D. ..... .1,000 U S P. Units
Vitamin B_1.. . . 666 U.S P. Units
Vitamin C ....50 mg , 1,000 U S P. Units
Vitamin E.....Alpha Tocopherol, 1 mg.
Vitamin G (B_2)..... 2 milligrams
Vitamin B_6 .....50 micrograms
Niacinamide .....20 milligrams
Calcium Pantothenate ..... 1 milligram
Liver Concentrate (1·20) .....2 grains
Ferrous Sulfate . ... 1 grain

Puretest and U. D. products are obtainable only at Rexall Drug Stores where competent pharmacists carefully fill your prescriptions. For quality, convenience and economy in drug service and supplies, you can depend on your neighborhood druggist displaying the Rexall sign.

IODINE...A PREFERRED ANTISEPTIC

Its Action is Efficient

Safety from infection must be certain...and the trustworthiness of Iodine has been continuously demonstrated through many years of laboratory tests and clinical trials. Its action is both bactericidal and bacteriostatic. Aqueous Iodine solutions, for instance, are shown to be bactericidal against Staphylococcus aureus and E. coli in dilutions approximately as high as those showing bacteriostasis. • Iodine can be relied upon to prevent infection when used pre-operatively, and in the treatment of wounds and abrasions.

AT HOME OR AWAY
SPOT TESTS
SIMPLIFY URINALYSIS

NO TEST TUBES · NO MEASURING
NO BOILING

Diabetics welcome "Spot Tests" (ready to use dry reagents), because of the ease and simplicity in using. No test tubes, no boiling, no measuring; just a little powder, a little urine—color reaction occurs at once if sugar or acetone is present.

Galatest
FOR DETECTION OF SUGAR IN THE URINE

Acetone Test (DENCO)
FOR DETECTION OF ACETONE IN THE URINE

SAME SIMPLE TECHNIQUE FOR BOTH

1. A LITTLE POWDER  2. A LITTLE URINE

COLOR REACTION IMMEDIATELY

A carrying case containing one vial of Acetone Test (Denco) and one vial of Galatest is now available. This is very convenient for the medical bag or for the diabetic patient. The case also contains a medicine dropper and a Galatest color chart. This handy kit or refills of Acetone Test (Denco) and Galatest are obtainable at all prescription pharmacies and surgical supply houses.

Accepted for advertising in the Journal of the A.M.A.

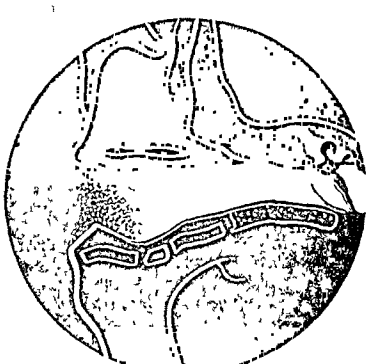
NEW, More Effective Topical Chemotherapy for Common Otologic Infections



White's **OTOMIDE** is a stable solution of sulfanilamide and carbamide (urea) in glycerin of high specific gravity. Anhydrous chlorobutanol, a recognized local anesthetic agent *that is therapeutically compatible with sulfonamides*, is included in the formula for its analgesic and antipruritic properties.

FORMULA:

Carbamide (Urea)	10%
Sulfanilamide	5%
Chlorobutanol (anhydrous)	3%
Glycerin (h.sp.gr.)	q.s.

Therapeutic properties of Carbamide component of Otomide:

1. Chemically debrides lesion by solvent effect on necrotic tissues.
2. Renders sulfanilamide effectively antibacterial even in the presence of pus.
3. Solubilizes sulfanilamide, effects higher tissue concentrations of sulfonamide.
4. Increases diffusibility of sulfanilamide through living and dead tissues.
5. Is free from irritating effect on living tissues.

INDICATIONS: Local management of suppurative and non-suppurative infections of external auditory canal.

White's Otomide is available in *dropper bottles* of one-half fluid ounce (15 cc.).

IMPORTANT: Please note that your patient requires your prescription to obtain this product *from the pharmacist.*

White Laboratories, Inc., Pharmaceutical Manufacturers, Newark 2, N. J.

White's

OTOMIDE

for
accessible
infections

Used in the form of irrigations or wet packs, Tyrothricin, Parke-Davis, is effective against many gram-positive organisms.

Its antibacterial activity against streptococci, staphylococci, and pneumococci makes it of real therapeutic value when these organisms predominate in:

- Superficial indolent ulcers
- Mastoiditis
- Lesions of the skin and soft tissue
- Empyema
- Osteomyelitis
- Ear, nose, and throat infections.

TYROTHRICIN must not be injected. It is intended *solely for topical use* in the treatment of superficial infections, deeper infections made accessible by surgical procedures, and infections in body cavities in which there is no direct connection with the blood stream.

Supplied in 10 cc. vials, as a 2 per cent solution, to be diluted with sterile distilled water before use.

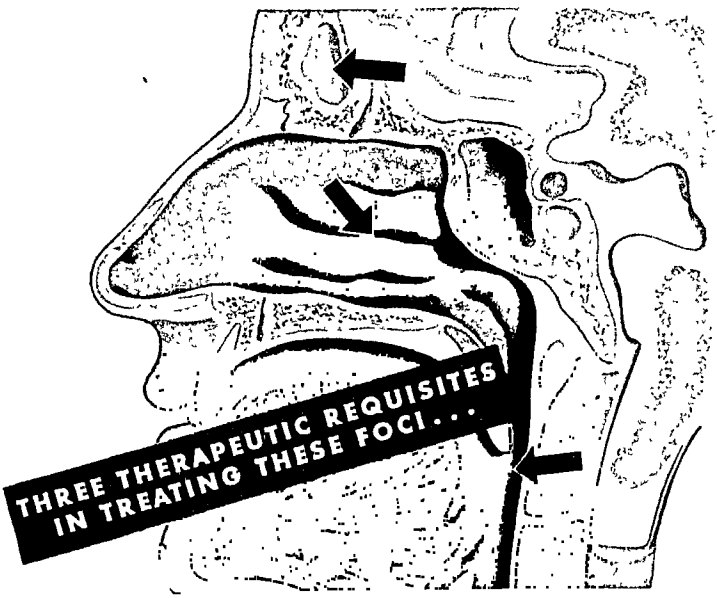
Tyrothricin
PARKE-DAVIS

PARKE, DAVIS & COMPANY, *Detroit 32, Mich.*

Nutritive Therapy

When the nutritive status of any patient is severely impaired, supportive therapy centers about four essential measures[1].

1. High caloric, high protein diet, within the tolerance of the patient.
2. Prompt administration of thiamine, riboflavin, niacinamide and ascorbic acid *in dosage which clinical experience[1,2] has shown to be effective.*
3. The natural B complex[1] in adequate dosage.
4. Additional administration of vitamins[2], calcium, and iron, if and as indicated.



Specific vitamin deficiencies, excepting in the case of vitamins D and K, are usually symptomatic of generalized nutritive failure. Many seeming contradictions in the literature become clear when this is understood. Use of the specific vitamins alone is at best symptomatic treatment and will not restore the patient to full health.

For documentation of this new concept, write on your prescription blank, "Nutritive Therapy." Send to Squibb Professional Service Dept., 745 Fifth Ave., New York 22, N. Y.

SQUIBB Nutritive Agents

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

IN PARANASAL INFECTION, the treatment with ARGYROL is wisely directed to these three foci:

1. the nasal meatus . . . by 20 per cent ARGYROL instillations through the naso-lacrimal duct.
2. the nasal cavities . . . with 10 per cent ARGYROL solution in drops or by nasal tamponage.
3. the fauces and pharynx . . . by swabbing with 20 per cent ARGYROL solution.

Marked relief generally follows because ARGYROL offers more than effective antisepsis, decongestion without vasoconstriction, and cleansing of the membrane. It provides also for stimulation of the membrane's inherent, natural defense mechanism

HOW ARGYROL ACTS

DECONGESTIVE—ARGYROL'S decongestive effect in the membrane is the result of its demulcent, osmotic action. The withdrawal of ARGYROL tampons from the post-nasal cavities frequently brings forth a long ropy mucous discharge measuring as much as two feet or more.

BACTERIOSTATIC—Although proved to be definitely bacteriostatic, ARGYROL is non-toxic to tissue. In nearly a half century of wide medical use of ARGYROL, no case of toxicity, irritation, injury to cilia or pulmonary complication in human beings has ever been reported.

STIMULATING—Soothing to nerve ends in the membrane and stimulating to glands, ARGYROL'S action is more than surface action. For it acts *synergetically* with the membrane's own tissue defense mechanism.

When you order or prescribe ARGYROL, make sure you specify Original Package ARGYROL.

The story of ERTRON

THE story of Ertron* is based on extensive and continuous clinical research in arthritis therapy over a period of ten years—as reported in a comprehensive bibliography.

The safety and effectiveness of Ertron has been proven in leading hospitals, universities, clinics and private practice. Work carried on under rigid conditions of control in all sections of the country has shown the value of Ertron in arthritis management.

The clinical work has been done on Ertron and the clinical results demonstrated in the bibliography apply only to this product. Ertron alone—and no other product—contains electrically activated, vaporized ergosterol (Whittier Process).

TO ERTRONIZE: Employ Ertron in adequate dosage over a sufficiently long period to produce beneficial results. Gradually increase the dosage to that recommended or to the toleration level. Maintain this dosage until maximum improvement occurs.

CONFORMAL Personalized SHOES

FOR MEN AND WOMEN

NEW AND REVOLUTIONARY

MOULDED TO THE INDIVIDUAL REQUIREMENTS OF EACH FOOT

The plastic arch built into Conformal shoe has *revolutionized* corrective shoe fitting. It eliminates guess work, assures absolutely accurate relief from strain in even the most acute cases. The best endorsement of Conformal shoes is that men and women leaders in the medical profession *wear* as well as prescribe them. Recommend Conformal shoes with utmost confidence—ideal for prenatal care. Your prescriptions faithfully followed by experienced fitters at:

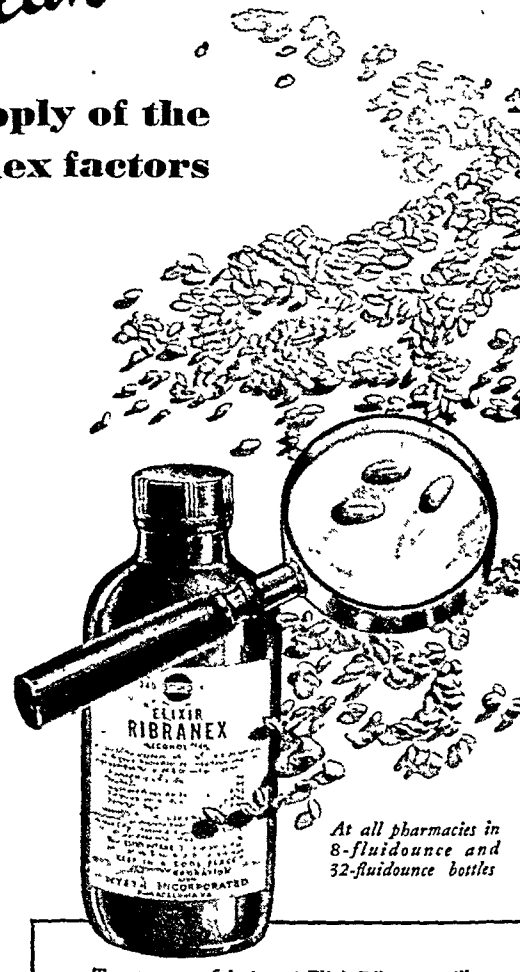
From Rice Bran

. . . a rich supply of the vitamin B complex factors

Knowledge of rice bran values has progressed rapidly since Eijkman's early work.

Rice bran extract, through years of comprehensive animal experimentation, has now been established scientifically as a highly desirable natural source of the vitamin B complex.



*Ribranex**, a potent elixir containing an aqueous extract of rice bran for prescription use, is made available to physicians through the facilities of S.M.A. Research.

The fine nutritional balance and the completeness of Elixir Ribranex were determined by long, painstaking assays conducted in comparison with several vitamin B complex preparations derived from other sources . . . The convincing results of this arduous work are recorded graphically for reference.

Elixir Ribranex provides the natural vitamin B factors present in rice bran with added crystalline thiamine, riboflavin and niacin amide.

All these potent vitamin B factors are preserved in a delicious sherry wine base.

Your patients will find Elixir Ribranex pleasingly palatable, especially well tolerated and well within average means.

At all pharmacies in 8-fluidounce and 32-fluidounce bottles

Two teaspoonfuls (8 cc.) Elixir Ribranex will supply the adult minimum daily requirements for thiamine hydrochloride and riboflavin together with niacin and niacin amide and other factors of the vitamin B complex as present in an aqueous extract of rice bran.

NOTE: *For treatment*—dosage may be increased at the discretion of the physician.

Editorial

An Adequate Diet, IV: Vitamins

This concludes a series of editorials, begun January 1, 1945, on "The Facts About Nutrition" prepared jointly by the editorial board of this JOURNAL and the School of Nutrition of Cornell University. The authors have consented to answer questions of readers pertaining to the contents of the editorials. Address inquiries to the Editor, NEW YORK STATE JOURNAL OF MEDICINE, 292 Madison Avenue, New York City.—*Editor*

It is in the field of vitamins that the largest recent additions to nutrition knowledge have been made. This continues to be the most active field of nutrition research. One might say that nothing since the first page of medical history was written has caused such widespread interest as the development of the appreciation of the role of vitamins. Because of this fact it is the responsibility of the physician to protect his patients from becoming the victims of needless and expensive vitamin therapy and to point out to them that vitamins are not a panacea for all human ills. The vitamin discoveries thus far made have resulted from experiments with several different species. One should realize that all of the recognized vitamins are not needed in the diet of all species. Generally speaking, all species require vitamins in their metabolism, but some species have the ability to synthesize certain vitamins within the organism. For example, the chick does not require vitamin C in its diet, whereas it is an essential constituent in the diet of man. Clearly, it is of primary importance to furnish these accessory food factors by an adequate diet rather than by the use of pills. In fact, an adequate diet is the only satisfactory means of providing a full vitamin intake.

In respect to man, we have reasonably good quantitative knowledge for planning diets and accessory food supplies in the case of vitamin A, vitamin D, thiamine, riboflavin, nicotinic acid, and ascorbic acid. Inasmuch as there are many gaps in our knowledge which need to be filled, the physician finds himself in a dilemma, for on the one hand he knows of the dramatic results obtained when full-blown deficiency diseases,

such as pellagra and beri-beri, are given intensive vitamin therapy; and on the other hand he hears, as do his patients, from the radio and popular articles that such symptoms as fatigue, constipation, anxiety, loss of appetite, and intellectual dullness are on a vitamin-deficiency basis; and, even though skeptical, he has at times also been victimized by lack of clarification. Carlson[1] puts it this way: "The public has been rendered vitamin conscious by the press, radio and by the less critical laboratory and clinical workers in nutrition. The detail man is eloquent and persuasive. So, lest we overlook a bet, we join the vitamin bandwagon."

Progress in research for determining the daily requirements of vitamins has gone through successive steps of endeavor. First came the successful experimental production of deficiency diseases in laboratory animals and their cure by supplemental feeding; second, the classification of foods as to their vitamin content, at first crude and later refined in method; third, the synthesis of vitamins; and, more recently, the discovery that many vitamins are synthesized within the body. The latter obviously raises the question of standards now used in calculating the daily allowances. Along the road where so many successes have been established in the last twenty years in the discovery of new nutritional factors, many discards are also strewn. This is true not only of vitamin research but of science in general. At any given place along the road we can only post the rules for that stretch of highway. The Food and Nutrition Board of the National Research Council, in the publication *Recommended Dietary Allowances*,[2] has posted the rules for the road thus far built. They provide a liberal factor of safety.

The daily allowance for vitamin A for the adult is considered to be 5,000 U.S.P. units. There is no variation in the requirement with body activity, but the requirement is higher during pregnancy and lactation and slightly lower for children to the age of twelve. The green leafy and yellow vegetables are the outstanding sources of vitamin A. An average serving of cooked greens, for example, will meet the daily requirement. Milk, butter, and eggs are also good sources of this vitamin.

Infants and children need supplemental addition to the diet of vitamin D. Not again until pregnancy and lactation is a supplement of this vitamin of proven value. Daily allowances of 400 to 800 U.S.P. units, the equivalent of one to two teaspoonfuls of U.S.P. cod liver oil, fulfill the required supplement.

There is some evidence that the American diet of today, because of modern processing methods, is low in thiamine. The physician will do well to investigate the thiamine content of his patients' diets. The recommended allowance for thiamine, which is now recognized to be unnecessarily liberal, ranges from 1.8 mg. to 2.3 mg. daily, the latter amount being advisable for those physically active, or during pregnancy and lactation. Pork is an outstanding source of thiamine; a 4-ounce serving of lean meat supplies about 1.7 mg. Whole-grain cereals, enriched flour, and bread are good sources to use every day. Foods such as meat, other cereals, peanuts, and some vegetables provide 0.1 to 0.2 mg. per serving.

The present recommended riboflavin allowances range from 2.2 to 3.3 mg. daily depending upon age, sex, and activity. For children under twelve, an allowance considerably less appears adequate. The requirements are highest with activity, increased body weight, pregnancy, and lactation. It is now recognized that the recommended allowances for riboflavin should be revised downward, on the basis of recent studies. Milk and meats are the most important sources of riboflavin, but they must be taken in considerable amounts to satisfy the daily requirement. Riboflavin is destroyed by light; hence, milk exposed to sunlight for any length of time no doubt loses a considerable amount of this important dietary essential.

The niacin or nicotinic acid allowance has been set at about ten times that of thiamine—18 mg. to 23 mg. for the adult, and somewhat less (4 to 12 mg.) before the age of twelve. Good sources of this vitamin are red meats and whole-grain or enriched cereals.

There are so many outstanding sources of vitamin C (ascorbic acid) that there is little reason for a deficiency of this vitamin where fresh fruits and vegetables are liberally available. In the preparation of vitamin C rich

foods for the table, particular attention must be given to avoid cooking losses. The daily allowance recommended for children up to the age of twelve is 30 to 75 mg.; from age twelve upward, 80 to 100 mg.; and during pregnancy and lactation, 100 to 150 mg.

Further information with respect to foods which supply the vitamins previously discussed can be found in the bulletin by Hewetson and Marsh.[3] With respect to the various other definitely identified vitamins, our knowledge of the role of most of them in the physiology of man and of their need in his diet is very meager. Vitamin K, which is essential for blood clotting, does not appear to be required normally in the human diet because it is synthesized by microorganisms in the intestine. Vitamin K therapy has proved most effective where indicated in certain special situations.

Much has been learned about the physiology of choline and the pathologic manifestations of its absence from the diet, but apparently human diets that are adequate in other respects can be relied upon to meet choline needs without the inclusion of special sources. It is known that choline can be synthesized in the body from other dietary constituents.

That man suffers from pantothenic-acid deficiency remains unproved. Its alleged role in preventing or curing gray hair seems definitely unconfirmed. Neither is there convincing evidence that supplementary vitamin E has any value in the human diet.

It has recently been shown that the intestinal synthesis of thiamine, riboflavin, and other B vitamins occurs in monogastric animals as well as in ruminants. Many have been found to be synthesized by man. This microbiologic activity produces complications in establishing dietary needs on a quantitative basis. Also, it raises the question of the indirect effect of the wide usage of the bacteriostatic sulfonamide drugs on intestinal organisms synthesizing B vitamins. Further studies may develop information of special significance in connection with the treatment of infections. They also may result in the discovery of B vitamins not previously recognized because intestinal synthesis normally meets body needs for them fully, irrespective of diet.

Such findings as these serve to illustrate the probability that there are other undiscovered factors of practical importance in certain physiologic or dietary situations and emphasize the necessity of an adequate diet which will supply the unknown, as well as the known, vitamin requirements. Too many people have their dietary sights focused on pills rather than on food. There is no scientific evidence that a well person on an adequate diet can be made "more well" in terms of immunity or strength, mental or physical, by taking synthetic vitamins. The wise physician will endeavor to correct the impression of modern youth that the products served at a soda bar supplemented by "pills" will meet nutrition needs. Can we criticize the younger generation when their elders, too, condone such practice? It is recognized, of course, that vitamin pills have, when indicated, a valuable therapeutic effect.

Ruffin[4] summarizes the use and abuse of vitamins as follows:

"1. Vitamin therapy is definitely indicated in patients having objective evidence of a deficiency state, but should always supplement dietary treatment, never replace it.

"2. Vitamin therapy is useful in preventing the development of secondary deficiencies in chronic wasting diseases and pre- and postoperative medical care.

"3. In the absence of organic disease, the individual who consumes a diet, adequate in calories, consisting of fruits, milk, eggs, a variety of meats, and green vegetables does not need additional vitamins.

"4. Vague symptoms such as weakness, fatigability, insomnia, nervousness, and irritability are more apt to be due to overwork, nervous tension, or to social, domestic, or financial difficulties than to a vitamin deficiency.

"5. For the most part, prolonged vitamin therapy in the absence of obvious disease is useless."

International Health

In these hectic days international affairs are in the limelight, but the question of war and peace is uppermost in public thinking. When the turmoil of war will have subsided into the calm of normalcy, international health inexorably will be a subject for fruitful discussion by international conventions. War breeds famine and pestilence, and the world has shrunk because of the amazing acceleration of transportation and communication. These are the natural precursors of the transition from a national to an international point of view about health problems. What form a world-wide health organization will assume depends upon the architecture of the world organization wrought by statesmen.

Quarantine regulations are the oldest accepted international health function, for it has long been recognized that certain diseases, such as cholera, plague, and yellow fever, have been carried by ships. During the past decade the rapid expansion of air travel, which promises to geometrically increase in peacetime, raises new and urgent problems. Air routes, to and from yellow-fever areas, from Africa, India, and other countries rife with pestilential diseases, demand a new international sanitary code. Recent studies in this field brilliantly illustrate the necessity of such regulations.[1]

Dangerous anopheline mosquitoes, carriers of malaria, have been transmitted between continents. The normal yellow-fever transmitter, Aedes aegypti, has been transported to Brazil from Africa. Epidemics of malaria and yellow fever soon appeared in regions previously free of these diseases. Precautions to prevent these infected insects from importing the virus of exotic diseases cannot be too stringent. Air travel threatens greater peril from the introduction of the insect than of the infected human being.

The United States must meet a similar problem when our troops return from Africa, India, China, and the far East. The influx of malaria carriers constitutes a definite challenge to the resourcefulness of our medical administrators. The great increase of malaria in our troops in tropical regions is of more than academic interest, as returning servicemen, importing new and virulent strains of malaria and other diseases, may become reservoirs of dissemination. The "invasion" of our country by malaria carriers has already been noted by the U.S. Public Health Service. The infected human being may infect a previously harmless mosquito which will then act as a transmitter of disease.

Influenza is a virus disease which has been in the past internationally disseminated. Different strains of this virus have been isolated and measures for immunization are being investigated.[2,3] A pandemic disease called influenza, frequently following in the wake of war, probably of viral origin, is still awaiting solution by preventive measures or some form of international prophylaxis.

Typhus fever, a scourge in war and in peace, is being conquered largely through international health centers. More effective delousing methods and more potent insecticides promise a speedier victory over this international enemy, through the agency of health centers equipped to carry out such procedures in conjunction with methods of immunization. Dysentery and diarrheal diseases will also respond to uniform and systematic methods of prophylaxis and treatment.

Nutritional diseases which are widespread in certain areas even in peacetimes, such as beri-beri, pellagra, and malnutrition due to protein and fat deficiencies, are also amenable to the methods of organized national and international health agencies.

International health functions will increase in future years. The ultimate goal is the establishment of efficient health centers throughout the world integrated and guided by a superstructure stemming from a world body. Full-time personnel will be trained for the dissemination and execution of the principles of medical prophylaxis and treatment for the extermination of preventable diseases, which rapidly move across boundaries unless controlled.

Symposium: Changes Which Have Resulted from the Use of Sulfa Drug Therapy

IN X-RAY FINDINGS IN MASTOIDITIS

WILLIAM RICHARD CASHION, M D , Flushing, New York

THE influence of sulfa drug therapy in changing the customary findings in x rays of the mastoids may be arbitrarily divided into three phases the first, in acute mastoiditis in which no bone involvement is present, the second in acute mastoiditis in which bone changes are present, and the third, in chronic involvement of the mastoid

The above classification was devised by me, as there are no other reports of this type in the literature, however, the observations which are to follow were observed first by Dr Law at Manhattan Ear, Nose and Throat Hospital, New York City, and were reported by him at a local otolaryngologic meeting

In the first phase, conventional films of an acutely inflamed mastoid showing severe involvement with no bone changes, the cell walls are seen to be fuzzy through the opaque veiling of the mastoid If sulfa drugs are given to the patient, the cell walls are thin and clear cut instead of fuzzy The entire mastoid is more transparent, similar to the hemorrhagic type The same observations are noted in the second phase however, the bony septa or cell walls which are softened or absorbed remain unchanged, neither progressing or regressing

In the first and second phases healing may take place completely and evidently does, as the incidence of mastoidectomies has dropped considerably in the past few years The discharge stops, temperature drops to normal and pain is relieved However, one must not be misled by these changes, for after sulfa therapy has been discontinued, the time varying from seven to ten days according to the type of drug given, there may be a flare up of the condition with recurrence of the symptoms Patients whose x-rays, taken at this time, show progression of the disease, are operated upon Those showing no changes in the disease, but showing clinical change in the judgment of the clinician, are also operated upon In all cases, the radiologic and clinical evidence is correlated There were several cases seen in which the general practitioner had given two, three, and four series of sulfa therapy

These cases eventually come to surgery This emphasizes that careful clinical observation plus x-ray findings should be followed during the course of the disease in order to determine the final disposition of the case

In the third phase, chronic involvement or repeated attacks of mastoiditis, the cell walls show varying degrees of osteitic thickening, therefore, the above observation does not follow There have been no changes seen in their appearance with or without sulfa therapy

Pathologic studies of mastoid cells following operation show the same changes with or without the drug There are areas of destruction and regeneration in both instances

I wish to thank Drs Law and Eggston for their assistance in presenting this paper

IN THE MANAGEMENT OF OSTEOMYELITIS

JAMES M FLYNN, M D , Rochester, New York

THE discovery of the sulfonamide drugs has been hailed with much acclaim by the medical profession This enthusiasm is soundly based, for it has been shown that they are capable of unbelievable good They do undoubtedly constitute one of the greatest advances in medicine of the present century

Yet it is well to be aware of the dangers involved in the indiscriminate use of these potent compounds There is a tendency on the part of some physicians to apply the drugs promiscuously, whereas it is of vital importance that the exact bacterial nature of every infection be determined, and also the degree of effectiveness of the sulfonamides to be used Those most effective are those few adjudged so from clinical experience, they have shown the least toxic reaction and hence are regarded as clinically useful

Believing that some physicians have gained an erroneous conception of the part to be played by the sulfonamides in the treatment of acute osteomyelitis or acute exacerbation of chronic osteo-

myelitis, I am attempting in this paper to fix their role as one of associated therapy rather than that of sole agent in the treatment of such infections. Bearing upon this purpose, I shall review briefly the findings obtained in a limited number of cases by some outstanding surgeon-investigators in this field of research.

Penberthy[1] concluded, after a study of a series of cases, that sulfanilamide was not effective in staphylococcal infections; that sulfapyridine with blood transfusions gave encouraging results; that sulfathiazole was the preferred drug because it was better tolerated. The method of treatment was as follows: $1^1/_4$ grains (0.08 Gm.) per pound of the body weight were given over a twenty-four hour period at four- to five-hour intervals. Following saucerization in chronic osteomyelitis, cavities were packed with sulfathiazole powder. It was found that chemotherapy considerably reduced the period of hospitalization as well as the incidence of metastatic abscesses.

Dively and Harrington[2] found the following procedure effective in the treatment of osteomyelitis: (*a*) systemic administration of sulfathiazole in sufficient dosage to secure a blood concentration of approximately 5 mg. per 100 cc. several days prior to operation; (*b*) thorough débridement of the infected area; (*c*) implantation of sulfathiazole crystals in the wound; (*d*) primary closure; (*e*) application of plaster dressing for fixation.

McKeown[3] found early and adequate administration of sulfathiazole combined with bone drilling to be effective in limiting the extent of the bone necrosis in the early stages of the disease, thereby preventing the establishment of a series of reactive changes which lead to chronic osteomyelitis. Key,[4] using sulfathiazole in the treatment of osteomyelitis, pointed out that the sulfonamides do nothing but inhibit the growth of bacteria. He stressed drainage of the focus of the bone to prevent increased destruction.

Dickson,[5] in a discussion of Key's report, stated that no matter how high a concentration of the drug is present in the environment of the bacteria, the sulfonamide-inhibitor substances, pus and necrotic tissue, must be reduced to a minimum. He recommended that the introduction of the drugs be preceded by a thorough surgical cleanup, pointing out that the primary factor of success is adequate surgery.

The authorities just called upon are of one mind as to the necessity of surgical intervention in the treatment of acute osteomyelitic infections. There are those who differ from this view. They hold to the belief that acute hematogenous osteomyelitis is a general disease or septicemia, of which the local focus in the bone is only one manifestation, and that the treatment demanded is one of a medical rather than a surgical nature. I cannot help but feel that this medical viewpoint arises from the fact that clinical signs, often disappearing after early administration of the drug, give rise to a false hope.

The view that early administration of adequate doses of the sulfonamides is not in itself sufficient to limit the severity of bone infection finds support in the experience of the roentgenologist. In a series of studies, by means of x-ray, of cases under sulfa-drug treatment, it can be shown that the clinical picture is often not very impressive. A condition far different from that which he was led to expect from the absence of clinical signs will confront the observer. The active progression of the disease, as revealed by the x-ray, will suggest immediate surgical intervention. Since the x-ray will reveal the exact location and extent of the infection, serial roentgenograms would aid greatly in the treatment of cases of suspected osteomyelitis.

The treatment of acute osteomyelitis infections demands adequate surgery in combination with the sulfonamides.

Several series of roentgenograms illustrating different phases of bone infection and following the use of sulfonamides and the change noted before and after surgical interference were shown and discussed by the speaker.

Discussion

Dr. Frederick S. Wetherell, *Syracuse, New York*— Dr. Flynn and Dr. Cashion, by implication, both reiterate the well-known surgical axiom which is applied to bone infections, *viz.*, that surgical intervention is indicated when bone necrosis occurs. They have made clear, too, that there may be abscess formation and tissue destruction even with absence of some of the clinical manifestations which ensued before the introduction of sulfonamides. They are correct in urging the use of serial roentgenologic studies of the diseased bone during the course of conservative medical treatment. It seems logical that the surgeon should be asked to see and to follow these cases while they are being treated conservatively. Surgeons are now beginning to see patients who have had long-continued medical treatment which included the use of sulfonamides. Bone destruction, including the formation of complicated sinus tracts, is often much more extensive in these cases than it would have been had there been earlier surgical intervention. Serial x-ray studies in such cases would have shown that the osteomyelitic process was not subsiding. Good surgery means that every bit of necrotic and infected bone has been removed, and that the longitudinal edges of the remaining bone are flat enough to allow soft tissue to fall over, and cover, the bone. With a correct technic the end result is good regardless of the type of chemotherapy which is used postoperatively. The preoperative use of such therapy has its value.

FILARIASIS

DONALD L. AUGUSTINE, Sc.D., Boston, Massachusetts

(Associate Professor of Comparative Pathology and Tropical Medicine, Schools of Medicine and Public Health, Harvard University)

FILARIASIS is much too inclusive a subject even for generalizations, and for this reason I have chosen to limit this discussion to just one of the species of the filarioid worms, Wuchereria bancrofti. This species is not only the most frequent, but is also one of the most important of the worm parasites of man in the warm countries. Its reported high incidence in our defense forces serving in or having served in endemic areas brings this parasite into particular prominence at the present time.

In 1863 small larval nematode worms were discovered in hydrocele fluid of a person in Havana, Cuba. Within the next few years identical worms were reported in chylous urine and in the peripheral blood of patients from different and widely separated parts of the tropical world. They were placed under the genus Filaria, a name established in 1787 and used by earlier authors in a very broad taxonomic sense. The adult forms of the parasite were discovered in a lymphatic abscess in 1876 by Brisbane in Australia. They were described under the name Filaria bancrofti. The parasite was generally known by this name until about twenty years ago, when, because of morphologic differences, it was placed under a new genus, Wuchereria, which name had been applied to the parasite in 1877 by Da Silva Araujo in honor of Dr. Wucherer, prominent physician and parasitologist at that time in Brazil. Today the valid scientific name of the parasite is Wuchereria bancrofti, and infection with it is generally referred to as bancroftian filariasis.

Although bancroftian filariasis is widespread throughout the warm countries, it is a focal disease, and is neither evenly distributed nor uniformly prevalent in any country. It characteristically occurs in island populations or along more or less broad, low-lying coastal areas of the larger islands and continents. Indigenous infections are seldom to be found in the foothills or beyond coastal plains. In Asia, the parasite is established along the coastal areas from Arabia to the Shantung Province in Eastern China. It is prevalent throughout the islands of the East China Sea, southern Japan, southern Chosen, and the Oceanic Islands. In Australia its distribution is mainly limited to the Queensland coasts. In Africa the infection is found in a few east and west coastal areas, Lower Egypt, Madagascar, and neighboring islands. Contrary to apparently current belief, it does not extend across tropical Africa; i.e., it does not occur in the Central Congo areas. For this information I am indebted to Dr. Paul Brutsaert, Director of Health Laboratories, Leopoldville, Belgian Congo. Brumpt[1] likewise, in his last edition of *Précis de Parasitologie*, does not include the Congo as an endemic area. In the Americas the infection is very common along the northern coast of South America, particularly the littoral of the Guianas and Venezuela, and to a lesser extent along the northern coast of Colombia, and is generally prevalent throughout the Antilles. This spotted and discontinuous distribution of the parasite within endemic areas is attributed to differences in local physical factors and sanitation, and to the presence or absence of favorable mosquito vectors. It is, however, difficult to understand why the parasite thrives along the northern coast of South America and throughout the Antilles, while there is a scarcity, if not absence, of indigenous infections along the Caribbean shores of Central and North America.

Within endemic areas, bancroftian filariasis is typically urban in distribution. It is restricted to a few towns or to sections of towns which are densely populated or poorly sanitated. It is particularly common in overcrowded dwellings of poor people, and the incidence and morbidity in a given family may be striking.

The adult worms are parasites only of the lymphatic system of man. They, like other nematodes, show marked sexual dimorphism; the male worm measures about 40 mm. in length and 0.1 mm. in diameter, and the female is at least twice as long. They may be found at any level of the lymphatic system, but occur most frequently in the limbs, scrotum, and inguinal regions. The two sexes are often coiled together in the periglandular tissues, the afferent lymphatics, and in the cortical sinuses. In heavy infections they may also occur in the medulla. Probably they do not migrate.

The progeny of the adult worms consists of very immature larval forms which, because of their minute size, were named microfilariae. Their appearance in the peripheral blood is periodic in most parts of the world; they are present at night but absent in the daytime. We

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1914.

have no adequate explanation for this phenomenon. These microfilariae, as seen in fixed and stained blood smears, are covered with a hyalin sheath which may extend some distance beyond the anterior and posterior limits of the body of the worm. These sheaths are not apparent on the microfilariae in the circulating blood. They are formed on the slide in the clotting and drying blood. The worm is mechanically held in the medium, and in its efforts to push on and back out, its outer covering is stretched. It usually does not escape, and the covering is retained as a distinct outer membrane. While the nature of the sheath is essentially an academic question, its presence is of practical value in that it forms a specific character in establishing diagnosis.

For further development and further spread of the parasite, the circulating microfilariae must be ingested by suitable mosquitoes, the sole vectors of bancroftian filariasis. The factors which determine the suitability of particular mosquitoes are not known. Development takes place readily in mosquitoes of a variety of genera, including Culex, Aedes, and Anopheles, but nearly related species within these genera differ widely in their ability to serve as hosts. For example, C. quinquefasciatus and C. pipiens are favorable hosts, whereas C. vexans is not; and A. scutellaris pseudoscutellaris is also a very favorable host, but A. aegypti and A. albopictus are not.

Metamorphosis and development of the infective stage for man take place in the thoracic muscles of mosquitoes. Under highly favorable conditions the infective stage is reached after about ten days when it travels through the thoracic muscles into the interior of the labium, where it awaits an opportunity to get back to man, which is presented when the mosquito feeds. Unlike the development of the malaria organisms in the mosquito, there is no multiplication of filaria larvae in the body of its vectors. On the contrary, only a fraction of the number of microfilariae ingested by the mosquito develop to the infective stage for man. It has been estimated that about 35 per cent of the microfilariae ingested by mosquitoes die in the stomach blood clot, and that a very heavy mortality of larvae may also occur after their arrival in the thoracic muscles.[2] These worms are pathogenic in the mosquito. Many infected mosquitoes die during the first few days after an infective blood meal. At every step of transmission, only a few parasites are involved. The transmission of bancroftian filariasis is, therefore, accomplished with much less certainty than that of malaria.

When the mosquito feeds upon a person, the infected larvae escape from the distal portion of the labium of the mosquito, and momentarily become free on the skin. They then actively enter the human host by penetrating the moist skin, entering presumably through the wound made by the mosquito, or through a breach in the skin.

Nothing is known about the larvae after they enter a human host until they appear as adult worms in the lymphatic system. Judging from observations on a related species in the dog, Dirofilaria immitis, development of W. bancrofti to functional sexual maturity probably requires at least several months. For production of microfilariae it is necessary that worms of opposite sex come to lodge and develop together in the same spot. Successful infections, therefore, probably are, in most cases, the result of mass biting by infected mosquitoes.

Giant urticaria, abscess, myositis, lymphangitis, lymphadenitis, elephantiasis, hydrocele, lymph scrotum, and chyluria are the commoner and generally accepted signs in bancroftian filariasis, although the manner in which the parasite produces disease is not clear. It is generally held that living microfilariae are not pathogenic. Our own experiments have shown that these larval forms readily pass unharmed through normal lymph nodes.[3] Direct observations have shown that they are exceedingly active in the blood stream. They are not only passively carried about with the blood stream, but they also actively move against the blood stream in the arterioles, making slow progress by bracing themselves against the walls of the vessel. They frequently occlude the capillaries, and then suddenly break through the stagnated column of blood cells to re-enter the active circulation. They apparently never make permanent plugs or form emboli.[4]

In view of the fact that microfilariae, in great numbers, are constantly being destroyed within the host, the possibility that at least some of the manifestations of bancroftian filariasis are allergic responses cannot be disregarded.

The serious disorders in bancroftian filariasis are usually attributed to the presence of the adult worms. O'Connor,[5,6] as a result of extensive studies on bancroftian filariasis in the South Pacific area and in the West Indies, was firmly convinced that dead adult worms, through aseptic degeneration and absorption, were chiefly responsible for the acute inflammatory processes which develop around them, and also for advanced pathologic changes. Here again an allergic sensitization to the worm's substance is assumed. Very recently Hartz[7] contributed significantly to our knowledge of the histopathology of bancroftian filariasis. According to Hartz, the living adult worm provokes dilatation of the parasitized lymphatic, and its subsequent occlusion and obliteration follow from a

granulomatous mass of epithelioid cells within the duct and a perilymphangitis Thus, in heavy infections we can expect extensive areas to be involved with obstruction of lymph drainage to a part, lymphedema to develop and elephantiasis, due to extensive fibrous overgrowth, to follow This sequence of events has been produced under experimental conditions by Dunker and coworkers [8]

I believe there is little doubt that W bancrofti per se can produce elephantiasis, but the question immediately arises as to the cause of the grossly identical elephantiasis prevalent in the Congo areas where the parasite apparently does not exist

Some authorities, Anderson[9] and Grace,[10] have been definite in the opinion that W bancrofti per se is not pathogenic, and that the pathologic manifestations usually associated with bancroftian filariasis, especially lymphangitis and abscess, are due to pyogenic organisms, particularly the beta hemolytic streptococcus which is of low virulence and characteristic of the tropics

Thus we have two distinct schools of thought One which holds to the view that W bancrofti is pathogenic and the sole cause of all pathologic manifestations associated with bancroftian filariasis, and the second, even more positive, that these same disorders, particularly lymphangitis, are of bacterial origin

Our present conception of clinical bancroftian filariasis is largely based upon observations by workers of the first school In their epidemiologic studies the populations have been divided into at least three classes (1) persons showing neither infection, i e , no microfilariae, nor accepted manifestations of filarial disease, (2) persons positive for microfilariae (usually upon blood examination), (3) persons with accepted signs or symptoms of filarial disease

In the last two divisions there is always considerable overlapping because some of the persons with microfilariae in the blood also show symptoms Most persons with clinical symptoms do not show microfilariae in the peripheral blood because of lymphatic block

There is considerable disagreement of just what should be included under "symptoms" or "signs of filarial disease" Buxton[11] and others hold that myositis and abscess in the Pacific area are not sequelae of bancroftian filariasis, but separate diseases due to a staphylococcus Lymphadenitis, and lymphangitis, particularly permanent enlargement of the epitrochlear gland, are considered, by Buxton and others, to be the earliest and cardinal signs of bancroftian filariasis, but Iyengar,[12] in his study of filariasis in India, excluded the presence of enlarged glands, lymphadenitis, and abscesses because he could not determine to what extent they represented filarial disease or filarial infection, but included elephantiasis, lymph scrotum, hydrocele, chyluria, and lymphangitis Buxton recorded hardness or enlargement of the testicle and epididymis and the presence of hydrocele as genital signs of bancroftian filariasis, but finding it difficult to define the boundary between a normal testicle and epididymis and one that was enlarged or fibroid, he concluded that the male genitalia do not provide useful physical signs of filariasis

Keen interest in the subject of bancroftian filariasis developed in this country upon the report of its alleged high frequency and its serious disabling effect in hundreds of patients in our defense forces who had served in the Samoan and other South Pacific islands While the cases thus far have been under military care, sooner or later many are bound to come to the attention of physicians in civilian practice

Among the chief complaints in these cases are scrotal lesions, funiculitis, epididymo-orchitis, edema of the scrotal skin, and lymphangitis and lymphadenitis The disease has occurred in troops who have had five months' or more service in endemic areas The diagnosis of bancroftian filariasis has been made almost entirely upon clinical signs and symptoms The rather sudden appearance of the disease is contrary to the usual train of events in bancroftian filariasis It is usual for the patient to harbor the parasite for months or years, as shown by microfilariae in the blood, without evidence of disease In the present group the disease suddenly appears, and microfilariae are not found in the blood

It has been my good fortune to study with Dr George C Shattuck a number of these cases returned from the Pacific area The following patient, seen privately, is representative

Case 1 —The patient, H W , a captain in the U S Marines arrived in Samoa in September, 1942 About mid-July, 1943, he became conscious of a slight transient swelling of the left testicle, slight pain horizontally across the left pectoral area and pain in the left forearm No swelling in the pectoral area was observed by him No microfilariae were found in his blood but the condition was believed to be due to filariasis, and he was returned to the United States

On September 21, 1943, he came to us for examination He appeared to be in good health The left testicle was found to be slightly larger than the right but this was not considered abnormal There was perhaps, some thickening of the spermatic cord but there was no evidence of edema or thickening of the scrotum The left pectoral muscle was thicker than the right The patient stated that he had not noticed this until it was discovered by a phy

sician who thought it represented swelling. Dr. Shattuck attributed this to asymmetric development and did not regard it as a pathologic condition. A 5 cc. sample of blood taken and examined at 11:30 P.M. was negative for microfilariae.

The patient stated that he wished to marry, but hesitated to do so because he feared embarrassing genital lesions might develop. After reassurance he felt greatly encouraged, and was told that there seemed to be no reason for not marrying. This he subsequently did, and when seen some weeks after the event he said he felt in perfect health, and that the early condition of the spermatic cord had disappeared.

Considering the wide variance of opinion on characteristic signs of filarial disease, there is no symptom in this case which can be attributed solely to infection with W. bancrofti.

It is not my intention to underestimate W. bancrofti as a human pathogen. There is sufficient evidence that it can be a factor in the production of the many clinical manifestations mentioned. The point I wish to make is that the evidence at hand is insufficient to warrant making a diagnosis of bancroftian filariasis for all cases from the South Pacific in which lymphadenitis, lymphangitis, or suggestive genital signs may have occurred.

The evidence presented by Grace that tropical lymphangitis can be a manifestation of hypersensitiveness to beta hemolytic streptococcus of low virulence should be reviewed and further studied. The onset of the attack of lymphangitis due to beta hemolytic streptococci, as described by Grace, is invariably sudden, and is ushered in with severe, deep-seated pain localized to a small area. This has been a characteristic feature of the histories we obtained in our studies on returned patients among military personnel.

I wish to recall here the early and important work of Dubruel[13] in Tahiti and neighboring islands. In this study, blood withdrawn in the absence of fever in cases of elephantiasis gave no growth on ordinary media, but that withdrawn at the height of an attack of lymphangitis yielded staphylococci in pure culture. It was also observed by Dubruel that fluid withdrawn in the presence of lymphangitis showed streptococci more frequently than that withdrawn between attacks. These observations of Dubruel are in accord with the results of the more recent experimental studies on elephantiasis by Drinker *et al.*[14] in which bacteria (streptococci) could rarely be isolated from edema fluid except at the beginning of an attack of chills and fever. In the light of these observations, the negative findings recently reported for navy and marine personnel with a diagnosis of bancroftian filariasis are not sufficient to rule out bacterial infection.[15,16]

It must be admitted that our knowledge of host-parasite relationships in bancroftian filariasis is largely an assemblage of ideas lacking experimental proof. But experimental proof here is difficult to obtain because man is the only mammalian host of W. bancrofti, and no filarial worm produces similar lesions in lower animals.

The problem is not an easy one. The fallacy of objective symptoms in the diagnosis of parasitic diseases has long been recognized. The answer must come through critical laboratory studies—helminthologic, bacteriologic, and histopathologic. For the present, a diagnosis of lymphangitis or lymphadenitis without specific reference to the filaria would dispel much of the nervous tension and fear which so frequently develop in these cases.

The question has frequently been asked—What is the prognosis for these cases from the Pacific? The answer must be uncertain, but the following case history, provided by Dr. Shattuck, indicates that deformity is not likely to result.

Case 2.—W. H., a 72-year-old man, was born in Dorchester, Massachusetts. He was graduated in 1895 from Harvard University, cum laude. Swelling and soreness of the spermatic cord began in 1923 shortly after his arrival in Tahiti from Sarawak. Epitrochlear adenitis was noted, and lymphangitis in the arms and legs, varying greatly in degree, recurred from time to time.

The spring and the summer of 1925 were spent in Maine, during which time the lymphangitis was rarely troublesome, but there was swelling of the left side of the scrotum on several occasions. Each time, nearly all of the swelling disappeared in about a week. There has since been practically no swelling of the scrotum. Early in 1926 he was examined by Dr. Manson-Bahr in London. No microfilariae were found in any of the specimens of his blood, and he was told by Dr. Manson-Bahr that he would probably have no further scrotal symptoms after returning to Tahiti, but suggested that it would be a matter of interest, but not great urgency, to have one of the affected glands in his arm removed. In 1929, after a recurrence of lymphadenitis in Boston, the right epitrochlear gland was removed. The freshly removed gland was examined by Dr. J. H. Sandground. No trace of filarial infection was found. The patient returned to Tahiti. A letter received by Dr. G. C. Shattuck from the patient, dated January 24, 1944, stated: "The favorable prognosis that Dr. Manson-Bahr gave me has been most satisfactorily fulfilled, for I have continued to live here with actually increasing comfort and now have nothing to show, so far as I am aware, except a double hydrocele and the very slightest swelling just above the right ankle, which I think you could detect only by pinching both ankles simultaneously.

"The Japs are now so far away, and getting farther, that the few men left at Bora Bora get bored and are given weekends here. I've seen many of

them since Bora Bora was occupied nearly two years ago, and I tell them that if they get filariasis there isn't one chance in 100,000 that the disease will ever bother them for more than a few months after their return to the U S A."

THE FUTURE OF MEDICAL PRACTICE

The manifold problems changes, and conflicts throughout the entire world are affecting every phase of our own individual lives, our political status as citizens and our national status as a nation, our economic status as breadwinners of families our cultural and intellectual status as examples to our children and our particular professional status as physicians

Most w
an over
to be al
really m
world wide social and economic revolution which may bring such changes in man's political, social, and economic life that we will have to go back to the Renaissance to find a change of similar magnitude. I do not believe anyone expects each and every change that occurs to advance man's happiness and security Some think the present trend may contribute to man s decay Only history will tell the answer

You all know by now that I am leading up to socialization of medicine and its enormous ramifications I do not believe we can consider this movement as a separate issue but rather as a development of this social economic revolution which particularly affects our lives as physicians You all have heard much discussion by physicians bitterly opposing such changes and by physicians favoring them We have heard or read what statesmen politicians, and labor groups proclaim, what educators economists and social workers debate, and what our own patients and friends say So far there has been much confusion and very little agreement and understanding Maybe there has been too great a desire to argue and not enough desire to understand

'Security" seems to be the word which profoundly affects the popular mind, and which most persons believe expresses
word is subject to
security is not poss
by virtue of a man's mortal existence some phases of our lives and actions are less secure than others and among the least secure is security from illness It is hard to see how edicts and laws alone enacted by well meaning socialistic governments, will alter the fact A streptococcus germ or an arteriosclerotic process will not obey such edicts

But we must face the fact that legislation probably will be enacted in the attempt to secure some form of health and sickness insurance, and some reason for this may be found among our faults and shortcomings both individually and as a professional group What are we going to do about it? Are we going to oppose and fight it in its every detail? If we do I fear we shall be badly beaten and have many harsh terms imposed on us This is because chivalry and magnanimity are seldom characteristics of a political victor Or, shall we attempt to understand what the public wants, try to find out how far we can help, how government can help the people and how they can help us to care for them

I do not believe I, or any man, has a definite solution but I do believe each of us has a definite duty to aid in the solution As members of our respective societies each should bear his share of the society's ever willingness to perform well Each must support the honest efforts of the local state and national committees, which are giving much time to the subject As individual doctors, each of us can do much with his own patients Each time we neglect a patient overcharge him humiliate him or even unwittingly criticize his other doctor, we hurt ourselves, our professional brethren, we lower the dignity of our profession and strengthen the cause of the more radical proponents of state medicine

If each of us will think more frequently of medicine as a profession, recall more frequently our Hippocratic Oath, polish up those ideals we all had when we were graduated and then make an honest attempt to practice that way—if each of us will do this, I am sure a meeting of open minds will yet arrive at a solution wherein the public will still
care from a doctor hon

A REVIEW OF RECENT FINDINGS IN FILARIASIS

DENIS R. A. WHARTON, Ph.D., New York City

(From the Department of Public Health and Preventive Medicine, Cornell University Medical College)

IN THE past year, and particularly in recent months, there has been published a large and varied body of data dealing with the symptomatology, diagnosis, and therapy of bancroftian filariasis. Most of this applies to the infection among personnel of the armed services and therefore has a special interest, inasmuch as it refers to a fairly uniform body of healthy adults exposed to infection under what we may call controlled conditions. It will not be irrelevant to remember that these men have been in the pink of condition, their life has been arduous under conditions of prolonged exposure, they have had access to a splendid medical corps, and have, in fact, been watched over continuously and keenly by it.

It is from this background that recent observations have been published, and although they vary in their degree of excellence, they all provide valuable data in one way or another.

Filariasis today may be recognized in many ways:

1. by clinical and physical findings;
2. by finding the worm on biopsy;
3. by x-rays showing calcified worms;
4. by the pathologic picture in tissue section;
5. by the presence of microfilariae in the blood;
6. by the cutaneous test.

Clinical Observations

The clinical findings comprise lymphadenitis and lymphangitis, principally of the extremities, the trunk, and the inguinal and genital regions. If the condition is one of lymphadenitis it will be conspicuous in the epitrochlear nodes, since it requires little enlargement in size for these to become prominent. The inguinal nodes, and the femoral nodes also, are among the first to show involvement.

Lymphangitis may be diffuse or it may be underlain by a tough, unyielding, cordlike hyperplasia. It was observed by Buxton several years ago to be preceded by lymphadenitis, and many of the present authors support this view. It is retrograde or centrifugal, not ascending.

The consequences of chronic prolonged lymphangitis, such as hydrocele, lymph varix, or elephantiasis, have not been seen, and in this regard it should be remembered that these are early cases and have been removed from the endemic areas with presumably more or less light infections. Lymphangitis and lymphadenitis have been considered by Buxton, and by Dassanayake, to be the early lesions of filariasis, and they are so considered by King.[1]

The subjective symptoms of bancroftian filariasis are pain and tenderness, fatigue, headache, drowsiness, blurring of vision, chills, fever, dysuria, backaches, and many others. Pain and tenderness are the most consistently observed symptoms and occur in the inflamed region, particularly the scrotum, but pain is not always present. In a series of 89 cases, 88 per cent experienced tenderness. Although pain is usually the first symptom, O'Connor[2] has noted many patients showing lymphangitis or even frank elephantiasis who were completely unconscious of their condition. In the same group of 89 cases, Johnson observed swelling in only 88 per cent. This is an interesting observation, as these cases may contribute to the sum of those who may later show microfilariae without observable symptoms, apart from such vague and variable ones as fatigue, headache, drowsiness, etc.

Fever occurs in a few cases; it is generally of a low grade, and lasts for two or three days or even weeks. The lymphangitis and accompanying symptoms recur every few weeks, or months, or years, but it is thought that after every remission it becomes more moderate. This is the observation made of the infection in a fair percentage of the service troops, but it is by no means general. In not a few the change has been imperceptible or for the worse.

Malaise is conspicuously infrequent, although Michael[3] notes it among the usual symptoms.

Pathology

If we make a biopsy of the affected gland or lymphatic, we may, upon making an incision, come across a thin, hairlike worm a few centimeters in length occupying the afferent lymphatics or the spaces of the gland. The worm may be living. Michael[3] has proposed a useful rough-and-ready way to save time and labor by cutting through the node and immersing it in saline at 37° C. After twenty-eight hours or so the worm will have worked its way out of the node into the saline. This may be done freely when one has no hesitation about performing biopsies, and Michael hasn't—in fact, he thinks them beneficial—but

As presented, with slight changes, to the New York Society of Tropical Medicine, November 30, 1944.

the worm may be dead or absent, and so tissue sectioning must be resorted to

In tissue sections the inflammatory process may be followed from its early stages to its resolution and fibrosis If the worm should be in the node, the cortical and medullary sinuses are greatly enlarged, and there is a dense granulomatous zone of macrophages and argentophilic reticulum having as its border variable members of eosinophils, lymphocytes, and foreign body type giant cells At times the tissue eosinophilia is marked These are the main changes, and they are duplicated in those inflamed nodes in which no worms are found The subcapsular nodules may be hyperplastic increasing in number and size

Wartman[4] finds that the lymphatic vessels display a variety of lesions, such as (1) hyperplasia of the lining endothelium and of the reticular cells in the walls, (2) acute lymphangitis with or without thrombosis, and (3) fibrous obliteration Occasionally simple lymph thrombosis occurs in vessels which otherwise appear normal

A common lesion is swelling and hyperplasia of the reticuloendothelium of the lymph vessels accompanied by perivascular exudation of eosinophils Occlusive thrombi composed of coagulated lymph and lymphocytes are frequent, and become infiltrated and transformed into a dense fibrous tissue They may at times be seen surrounded by endothelial cells and suspended by strands of these to the wall

Hartz,[5] reporting from the Dutch West Indies, described a pathologic picture which is essentially the same as that described by Wartman In fact, Hartz's report is some months earlier He says that the epithelioid cell granulomatous endolymphangitis, especially when combined with epithelioid cell perilymphangitis and eventually with the changes in the lymph nodes, must be considered as fairly typical of filariasis In several of his cases the presence of the typical histologic lesions was the reason for his examining several more blocks of tissue which led to the finding of the filaria Both Hartz and Wartman are in agreement on this Michael considers tissue sectioning indispensable and they have the support of most of the recent authors reporting on the pathology of the disease Wartman feels that the lesions are characteristic of filariasis, as they are not formed where filariasis does not occur

Burhans and his associates, however, object vigorously to the diagnostic value of the pathologic findings, and consider that the condition can be seen in any node which has reacted to a toxic substance But they find laboratory data in general useless as a diagnostic aid "Our only support," they say, "for the diagnosis of filariasis was the clinical and physical findings" Nevertheless, when a gravid female worm was later found in a patient originally from the same unit but at another hospital, they considered their diagnosis confirmed

King[1] believes that the diagnosis can be established clinically with very little doubt and that the history of a prolonged stay in an endemic area, the finding of lymphangitis of the extremity, trunk, or genitalia, coming on after an interval of at least three months, combined with adenopathy, eosinophilia, and a positive intradermal reaction, completes the characteristic picture of early filariasis

It should be pointed out here that these findings elaborate upon but essentially confirm those of O'Connor and Hulse,[2] who made their report over twelve years ago

The inflammatory reaction appears to dispose of the worm in two ways Within the vessel a thrombus composed of coagulated lymph and lymphocytes, with some infiltration of eosinophils, macrophages, and giant cells, grows by coagulation and the accretion of cells until it literally strangles the worm Or occlusion of the vessel, and hence strangulation of the worm, may result from the inward pressure of the proliferating reticuloendothelial cells In either event, the macrophages systematically devour and remove the worm with, of course, tremendous loss to themselves But it sometimes happens that the process is interrupted by the formation of alkali soaps, according to Michael, and the deposition of calcium salts in the cuticular membrane Such calcified worms may be detected readily by the use of x-rays, as demonstrated by Golden and O'Connor[6] and substantiated by Burhans and associates and by Greig

A summary of pathologic studies shows that lymphangitis and lymphadenitis may result from the presence of living or dead adult filariae within the affected nodes or lymphatics, or elsewhere These studies stress the fact that the living worm is an offender, as against the view held by some of the earlier workers, notably Manson and Leiper, that the living worm was innocuous It must be said, however, that it is some time since insistence has been put upon the death of the worm as a prerequisite for the inflammatory process Thus O Connor and Hulse[2] thought it "possible that the healthy adult worms are not responsible for the more striking of the changes observed The nature of the reaction becomes more marked, and also changes with advancing disintegration of the parasites" At any rate, no one familiar with the antigenic mechanism of the nematodes could take that position, although certain texts definitely need revision in this matter

TABLE 1

	Clinical Cases	Percentage Negative for Microfilariae
Fiji Is. (Bahr)	417	63.6
Ceylon (Bahr)	52	92.3
Amoy (Manson)	65	41.5
Ellice Is. (O'Connor)	335	52.1
Tokelau Is. (O'Connor)	49	71.4

Madras (Cruickshank *et al.*)	758	79.9
India at large (Acton and Rao)[9]	2,003	92.3
S. Pacific Is. (Lowman)	201	84.1

Careful examination of excised nodes has failed to reveal the presence of bacteria either in culture or in stained sections. The presence of the worm alone, or of its products, appeared to suffice to produce the changes recorded. The absence of leukocytosis or of high fever does not fit the pathologic picture of bacterial origin, nor does the retrograde nature of the lymphangitis. In this O'Connor appears justified, and the contention of Grace and certain other authors that streptococci are the exciting cause, while undoubtedly applicable in certain cases, does not appear to be generally tenable.

Epidemiologic Considerations

It has been thought that the filarial worm, i.e., W. bancrofti, took about a year to complete its cycle in man, and this belief was founded on considerable clinical and epidemiologic evidence. Hence it is not to be expected that our troops who have shown clinical evidence of the disease eight or nine months after exposure to infection will present blood positive for microfilariae. Even those who have been infected for over a year have been negative. This accords with past observation and normal expectations, and with what is known about the length of the life cycle of certain filarial worms. In this connection Bancroft recovered adult Dirofilaria immitis from the dog seven months after mosquito transmission, and adults and microfilariae nine months after infection. This was confirmed by Fülleborn, who recovered microfilariae eight months after mechanical inoculation. D. scapiceps from the snowshoe hare has completed its development in the domestic rabbit in eight months. It is surprising, therefore, that the opinion should have been expressed in responsible circles that the prepatent phase of the infection in the infected men is so prolonged as to require a revision of clinical and laboratory diagnostic methods. The earliest record of the finding of microfilariae in the blood, made by Sweet and Pillai in India, was in that of a child somewhat less than a year old.

A report, made by Flynn,[8] on 125 patients from the Pacific, states that 8 cases were positive for infection in their blood or lymph-node aspiration fluid. The average length of time between first exposure and symptoms was 10.2 months, the longest fourteeen, and the shortest eight months. These are the first cases of positive bloods mears published, and the appearance of microfilariae comes within the roughly established range.

The idea that the prepatent period is unduly extended has its counterpart at the other end of the scale. Michael, stating that the symptom-free period varied greatly from one to twelve months, nevertheless says, "Unquestionably at some time in the cycle of the parasite, microfilariae were present in the circulating blood, but this occurred long before clinical symptoms ever developed." This would imply the maturing of the parasite in a handful of days at most, which certainly would be exceptional.

Yokogawa claimed to have found microfilariae in one hundred and eleven, eighty-two, and fifty-six days after infection in volunteers. The microfilariae were found in one case fifty-six days after what he calls a second infection. But neither in this nor in his group of volunteers did he give assurances of prior freedom from infection. In fact, he believed that W. bancrofti could mature and produce microfilariae in as few as twenty days. This notion is mentioned here merely as a matter of record.

In filarious individuals, especially in children and adolescents, it is common to find microfilariae in the blood and no physical signs of the disease whatever. The observation is common, not absolute. But it is also frequently encountered that individuals with signs of the disease fail to show microfilariae. This does not refer merely to cases of elephantiasis, in which this lack is fairly general, but to all cases, and from different parts of the world. In the accompanying table the findings are stated in terms of the per cent of clinical cases without microfilariae in the peripheral blood.

Similarly, Hoffman and associates,[10] in Puerto Rico, found a high percentage of clinical cases without microfilariae.

It thus appears that filariasis as it occurs among our men may well reflect a commonly observed characteristic of the infection. The observation is tentative, for, in fact, the infections are so recent that we know too little about them to make generalizations or comparisons with other groups, though it may be found in time that the Atlantic and Pacific strains have significant differences.

The reasons for symptoms without microfilariae, and vice versa, are not all known. But, acknowledging the fact that the antigenic activity of the living worm is a functional matter, that is to say, the exudations from the mouth,

anus, and excretory pore are antigenic, it follows that the worm in the course of its development is constantly sensitizing the body. As it becomes lodged in the lymphatics the local irritation is intensified, and the entire reaction is aggravated, by the seminal fluids of the male and the uterine secretions of the female worm at the time of copulating and hatching. In such a case, inflammatory symptoms may appear without the presence of larvae, such as in fact occurs in early cases. Certain sensitive individuals would naturally be reactive at an earlier date after infection than others, and, of course, the death and disintegration of the male and female worms would be an important factor.

Wartman suggested the imprisonment of the microfilariae in the granulomatous tissue as a possible reason for their lack in the peripheral circulation. This may be, but it seems more likely that the parent worms were immature, since there were no microfilariae in the sinuses or lymphatics outside the worms. In immune persons, however, it is probable that the microfilariae get beyond the inflamed area with difficulty, if at all, being quickly destroyed by the aroused macrophages. In fact, O'Connor finds these sites a veritable graveyard for the microfilariae, and undoubtedly this is the mechanism of many an abortive infection.

Again, a nice balance may be struck between the host and parasite, both living in comparative harmony, the infected person showing microfilariae without signs or symptoms.

There is much to show that adult worms are killed, digested, and removed with nothing but fibrotic tissue to indicate that they had ever been there. Where this has happened on a sufficient scale to obstruct the lymphatic trunks, lymph stasis may be so complete as to result in elephantiasis without microfilariae.

Diagnosis

An increasingly important feature of diagnosis is the use of the cutaneous test for hypersensitiveness. The methods employed are those of Taliaferro and Hoffman,[11] and of Fairley.[12] In infected individuals they have proved to be approximately 90 per cent positive and have been about 90 per cent negative in healthy persons. D. immitis from the dog is employed as the antigen and 0.1 cc. of a 0.1 per cent saline extract is the usual dose. It is interesting that neither Fairley, nor Taliaferro and Hoffman found false positives shown in individuals harbouring species of helminths other than the filariae. The reaction is group-specific. King has made extensive use of this test and considers it highly dependable, and his results confirm those of the previous authors. In fact, in a group of 241 persons who had spent some months on Samoa but showed no signs of filariasis, 45 per cent were reactive, indicating that a considerable amount of subclinical filariasis exists. This fits in with the previous remarks on immunity and the statement that it is too soon to draw any more than tentative conclusions as to the status of the infection in our troops. It must be said that van Hoof, in the Belgian Congo, felt that the test was not sufficiently specific for use in natives who were heavily and variously parasitized. He was applying it to detect infestation with Onchocerca, but in view of the fact that other filarial infections and onchocerciasis itself of a subclinical nature exist in this region, this objection must be treated with caution. Yet Wright and Murdock, making tests with 1:2,000 and 1:4,000 dilutions in Guatemala, considered their tests nullified by other helminthic infections.

To overcome this objection, which the vast mass of data does not support, Bozicevich and Hutter[13] prepared an antigen in a dilution of 1:8,000 and used 0.01 cc. of this for the test. Excellent results were obtained in 25 patients diagnosed clinically as filarious, but without microfilariae in their blood. False positives in noninfected and allergic persons were successfully screened out.

Interestingly enough, in 7 of these patients the injection was followed by an exacerbation of lymphangitis, and in 8 by pain in the scrotum and lymph glands, particularly the inguinal. The much stronger doses of antigen employed by other authors have rarely resulted in such a show of hypersensitiveness. This, however, is undoubtedly the basis of the fugitive swellings sometimes observed.

As mentioned earlier, x-rays may be of use in detecting the presence of filarial worms in the lymphatics when the worms are calcified.

Treatment

The treatment of filariasis has hitherto been largely symptomatic. This has consisted in removal of the patients from the endemic area so as to avoid, if possible, massive infestation, to provide a change of climate, and to afford rest.

Cooler climates and rest have been found favorable in reducing lymphangitis and lymphadenitis, and undoubtedly this must be due to the fact that the lymph flow is slowed up under these conditions, whereas under the influence of exertion or warm weather the flow is stimulated and lymphangitis recurs. According to Johnson, exertion was responsible for renewed attacks in practically all cases, and warm weather in half of them. Johnson gives data that tend to show that there is a better chance of improvement the longer the stay in the United States, but at present it would

appear that improvement is temporary and conditioned on rest and a cool climate.

O'Connor has used x-rays with some success, especially in chyluria and to a lesser degree in lymphangitis. Burhans and associates recently reported very favorably on the use of x-rays, but reserved comment as to the ultimate outcome of treatment.

For a time it looked as if anthiomaline, as used by Brown, might fill the need of an effective therapeutic agent, but this appears due to be discarded.

Mapharsen has been tried by King with suggestive results, but it requires more careful trial before being put to general use in this infection. This is so because of the danger of suddenly killing the worm and releasing a sufficient quantity of antigenic material to cause severe lymphangitis or other manifestation of allergy. This, in fact, happened in some of King's patients, but until the effect of the drug is tried experimentally, the reason for this—and the effectiveness of the drug—can only be guessed at. The prospects for the satisfactory treatment of infected persons are therefore in doubt.

In this regard emphasis should be placed on the correct psychologic attitude of the patient. When the patient is informed as to the outlook his condition usually improves from the state of mental depression into which he may have *been permitted to slip.*

As a prophylactic measure it might not be unprofitable with persons recently exposed to infection, to inject an antiserum of high titer together with small doses of antigen, the object being to so raise their level of immunity as to lift it above the point of hypersensitiveness, and hence avoid lymphangitis and lymphadenitis. But this is as yet conjecture.

Conclusion

The question naturally arises whether filariasis is apt to be a menace in this country. In the light of present methods of coping with the infection it is probable that in many of the patients the infection will terminate spontaneously; those who remain infected will probably have relatively few microfilariae in their blood, and these may be reduced, but not eliminated, by chemotherapy. In any case, the living habits of the majority and a temperate climate will probably preclude the likelihood of the establishment of endemic centers here. Should a large body of troops from the South become infected, however, there is a definite likelihood of the appearance of endemic centers in the South. There are several species of mosquito fully capable of maturing the infective larvae. In a recent report of tests to determine the ability of domestic mosquitoes to transmit W. bancrofti, Newton and Wright found 100 per cent of Culex quinquefasciatus capable of maturing the larvae to the infective stage; 67 per cent of Anopheles albimanus; 12 per cent of Psorophora confinis; 6.8 per cent of C nigripalpus; 4.9 per cent of Aedes aegypti. And C. pipiens is known to be able to do so.

It is not improbable that the physician will come across cases in his practice which will tax his knowledge of tropical diseases. The present article has been written to provide a sound general understanding of the problems presented by filariasis.

MEDICAL SOCIAL SERVICE COUNCIL DISCUSSES NEEDS OF SERVICEMEN

The Medical Social Service Council of the United Hospital Fund of New York held a meeting on the subject, "Wartime Developments in Hospital Care and Social Services for Servicemen and Veterans," on Tuesday, January 16 from 3:00 to 4:30 P.M. in the Einhorn Auditorium of the Lenox Hill Hospital.

Maj. Donald A. Covalt, MC, Executive Officer of the Convalescent Training Division, Office of the Air Surgeon, spoke on "Rehabilitation in the Army Air Forces." After Major Covalt's talk an Army Air Force Motion picture, "Out of Bed into Action," was shown.

Hospital and medical needs of returning servicemen were discussed by Louis Bennett, director of the Veterans Service Center in New York City. Reports by social workers in special veterans' clinics informed the Council of the social services available for veterans in the hospitals of New York City. Mrs. Curry Watson, chairman of the Medical Social Service Council of the United Hospital Fund of New York, presided at the meeting.

MEDICAL ASPECTS OF RECALCITRANT AND COMPLICATED ULCER

SARA M. JORDAN, M.D., Boston

(From the Department of Gastroenterology, the Lahey Clinic, Boston)

THE adjective "recalcitrant," if interpreted literally from its Latin derivation, means "kicking back," and in its broader sense is interpreted by Webster as "stubbornly rebellious" and "obstinate in defying constituted authority." The purpose of this paper is to attempt to analyze not only the factors which cause the kickback of ulcer but also the behavior of this "constituted authority" which meets with defiance in these recalcitrant cases. Or, to speak without allegory, I should like to discuss with you the problem of what ulcer does not heal or stay healed, and why.

As we older clinicians accumulate what we like to call knowledge and wisdom, again by virtue of our age we like to indulge in reminiscences. One most clearly stenciled in my memory is of a modest but cogent statement made by Dr. Ivy at an American Gastro-Enterological Association meeting some years ago when, after reviewing the work he and Mann had done upon the production of experimental ulcer in animals, he said something like this: "We have demonstrated that ulcer can be produced in various ways, chemical and mechanical. We can go no further with animal experimentation. We have reached an impasse beyond which lives the human being and his ulcer with its chronicity and its tendency to recurrence. That is your field, gentlemen."

On that occasion, I am sure we who were working with the problem of ulcer treatment were given a new stimulus to build on the foundation laid by these physiologists, and to add to their experimental observations our clinical experience in an endeavor to solve the problems relating to peptic ulcer.

On this occasion, therefore, before discussing the recalcitrant ulcer, it is fitting that we survey current opinion on the nature of peptic ulcer. The importance of this disease becomes constantly more impressive. Its high incidence and its disabling character are a distinct impediment to the present war effort and to sustained work on the home front. Hence the time is opportune for another review of the ulcer problem.

The physiologic experimental work of Ivy and Mann elucidated the nature of this disease to the degree that it became obvious that mechanical and chemical factors, as evidenced by spasm and hyperchlorhydria, are basic in the production of ulcer. Clinical observations confirm their findings and emphasize the importance of them. We find hypertonus and spasm combined with hyperchlorhydria not only in the presence of actual ulcer but also in the precursor stage of both the original ulcer and the recurrence.

Under the influence of cumulative experience with this disease, certain clinically substantiated premises may be formulated, chief among which are:

1. There is a group of persons who under certain conditions are prone to develop peptic ulcer and recurrences.
2. Hyperchlorhydria and spasm play a major role during the activity of the ulcer.
3. Treatment, to be effective, must be directed toward these two factors, and healing is attended by release of spasm and irritability and reduction of acidity.
4. The precipitating influences in recurrence are, in the order of their importance:
   (*a*) Psychogenic group (fatigue, nervous tension, and emotional disturbances)
   (*b*) Smoking
   (*c*) Dietary indiscretions
   (*d*) Alcohol
   (*e*) Neglect of routine rest and exercise

A brief consideration of these premises suggests that there is no definite type of human being who is prone to ulcer. The doer and the worrier, that is, the effective person who meets the experiences of life seriously and conscientiously, probably is the most frequent victim of this disease. Yet we are constantly confronted with the person who appears entirely carefree and light-hearted between the episodes of ulcer activity. However, probably most of us would agree that in peptic ulcer and likewise in ulcerative colitis, the conscientious striver most often is affected. In our experience, there is definitely no physical type of person who is more prone than others to develop an ulcer. Both sthenic and asthenic individuals are well represented in the ulcer group.

The role of sustained muscular contraction and irritability of muscle associated with hyperchlorhydria definitely has been established by experience. Hypertonus, pylorospasm, and duodenal irritability are an integral part of ulcer activity, as evidenced by hyperchlorhydria. In fact, without these findings an active ulcer hardly can be diagnosed. It is, of course, recognized that with the gastric ulcer the acidity is usually within normal limits and that with the [illegible]al ulcer a range of acidity which

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 1944.

normal for the intact stomach can be considered abnormally high.

All treatment, both medical and surgical, is directed toward release of spasm and hypertonus and a diminution in acidity. The success of both medical management and gastric resection depends upon the attainment and maintenance of this objective.

The attainment and maintenance of ulcer healing is, by implication, the chief topic of interest in this discussion of the refractory ulcer. It is our belief that every ulcer is potentially healable, and that its refractory tendency is caused by certain fortuitous circumstances which have to do with the location of the ulcer and the behavior of the patient. The healing potentiality of every ulcer is vastly improved, we believe, by a detection of the ulcer before it has eroded too deeply into the gastric or duodenal wall, and an accurate regimen to promote and maintain complete healing. Early discovery is particularly important when the ulcer is located on the posterior wall of either the stomach or duodenum or in the second part of the duodenum in the neighborhood of the ampulla of Vater. In these three locations, deep erosions, often through to the pancreas or other adherent structures, make healing more difficult. The keynote of treatment must be adequate rest and neutralization, and in spite of the necessity for ambulatory treatment in these feverish days, we adhere to the belief that every ulcer which is causing severe enough symptoms to require medical help should be treated intensively, and if at all possible, with hospitalization, so that both rest and neutralization can be fully accomplished. It is both gratifying and interesting to observe the complete subsidence of even the most intense ulcer distress as these two therapeutic objectives are attained. In the severe cases, intensive methods must, of course, be used—constant neutralization, as with Winkelstein's drip, or with the drainage method devised by Dr. Wilkinson, of the Lahey Clinic, or with other systems.

Usually gastric ulcers can be followed to complete healing more graphically than duodenal or marginal ulcers, and when they are located on the posterior wall and show large craters, it is practically certain that they are burrowing through into the pancreas. Yet even some of these large lesions can be observed to heal completely, the fluoroscopic observations being supplemented and confirmed by gastroscopy. In our experience, the size of the ulcer has no significance as far as potentiality of healing is concerned, the largest often shrinking to disappearance more rapidly than some of the more persistent smaller ones.

That the potentiality of healing is lessened by complications is naturally true. An evaluation of this question depends largely upon statistics, and here it should be stated with emphasis that the statistics of ulcer cases are completed only with the death of the patient. We constantly are confronted with patients whose ulcer history, including both medical and surgical theory, occurred many years previously. For them and probably for their physicians the ulcer story had a satisfactory ending years ago, only to be reopened later with an unhappy chapter of recurrence. Only when we have a sufficiently large group of ulcer patients who have died either of their ulcer or of other causes shall we have satisfactory data as to their course after medical management or resection. This is especially true of the complication of hemorrhage.

At various stages in our ulcer experience, we have made policy rules for surgical intervention in the presence of complications. At the present time, however, we do not adhere to general rules but review thoroughly all the factors in the patient's case before deciding to initiate or continue medical treatment or to advise resection. Especially in hemorrhage, which we believe to be one of the most refractory of complications, our former rule of urging resection after two massive hemorrhages must often be ignored. Adequate medical management should, we believe, be used in every case, even after several hemorrhages, if it has not been previously tried. And by adequate medical management we mean complete rest and neutralization for a sufficient time to produce both clinical and roentgenologic evidence of healing, and a subsequent program for the maintenance of healing, including abstinence permanently from smoking and at least temporarily from alcohol and reasonable care in diet, rest, and exercise.

Adherence to such a schedule implies a complete understanding by the patient of the nature of his disease. He must be taught that the disease is not just a single lesion but is an indication of a systemic condition which must be managed just as diabetes and tuberculosis are managed. He must be informed that the history of hemorrhage indicates a possibility of further hemorrhage and that even with radical resection further bleeding has occurred; also, that while this operation may well offer him a better chance for freedom from this complication if the ulcer can be removed, failure to adhere to a postoperative regimen increases the probability of further bleeding from a new marginal ulcer. In other words, he must be told that a recalcitrant ulcer may occur after resection as well as in the intact stomach. With all these considerations in mind, if the patient has not yet conscientiously followed a good ulcer regimen and if he thinks

logically, he will wish first to try the effect of medical management before having this radical operation

The complication of obstruction may be both acute and chronic clinically Experience indicates that there actually are three groups of cases

1 Those in whom cicatricial fibrotic change has narrowed the lumen of the pylorus or duodenum to such a degree that normal function can never be restored
2 Those in whom there is a combination of cicatricial and inflamed tissue and in whom with the subsidence of inflammation the fibrotic tissue is still not too extensive to allow of good function
3 Those in whom the obstruction is entirely of an acute inflammatory nature, subsiding completely with medical management

The first group is definitely recalcitrant The second and third are amenable to medical treatment, even though the history and immediate serious condition appear formidable Usually a few days of medical treatment indicate whether there is a probability of permanent relief by medical management In certain cases of the second group a recurrence of obstruction may occur, and in such cases it is advisable to save the patient's time and money by performing a resection when the patient is first treated In an attempt to detect these cases, as well as those of group 1, in which cicatrix alone is the cause of obstruction, Dr Wilkinson, of the Lahey Clinic, originated a policy by which the patient is fed through a Levin nasal tube at regular intervals and allowed to drain likewise at regular intervals If the amount of drainage decreases within a few days, the obstruction is probably the result of temporary inflammation, and with the attainment and maintenance of healing, no further obstruction occurs If, however, the amount of drainage exceeds that of the intake and fails to decrease with treatment, the obstruction probably is cicatricial to such an extent that the ulcer is definitely recalcitrant and should be operated upon

Perforation in the acute form is, of course, a definite indication of recalcitrance and brooks no indecision as to the need for surgery The surgery in most cases is simple suture, and when ulcer later recurs in such a case the patient often fears another perforation In our experience, this is not in itself a reason for surgical intervention We believe that the same conditions hold for such an ulcer as for those which have never perforated —that they are essentially healable by medical management Subacute perforation with the formation of adhesions around the perforated area often remains undiagnosed until the failure to heal makes surgery necessary and the condition is revealed In other cases medical management is effective and only the pronounced and persistent deformity of the area around the ulcer suggests the presence of this condition

The gastric ulcer has one other form of recalcitrance which has been discussed extensively but which again merits brief mention in this paper, namely, malignancy Many gastric ulcers heal with medical management, some never to recur, and others show the same tendency to recurrence as duodenal or jejunal ulcers However, in certain of these recurrent gastric lesions malignant changes have been found, and in the light of experience we are now convinced that it is wise to consider the recurrent gastric ulcer as definitely recalcitrant because of the possibility of malignant changes

We have long used three criteria for benignity of the gastric lesion, namely, the disappearance of the lesion by roentgenologic and gastroscopic examination, the complete relief of symptoms, and the disappearance of occult blood from the stools We have added a fourth, namely, that the gastric ulcer does not recur

The tendency of ulcer to recur is its most unpleasant characteristic Even long remissions give no assurance of cure As I have already said, this fact makes it necessary for the intelligent person who has an ulcer to become thoroughly familiar with the nature of the disease He and his medical counselor must become the constituted authority which must not be defied by the recalcitrant ulcer The incidence of recurrence demonstrates not only the character of the disease but also, in my opinion, the fact that there is more undertreatment than overtreatment Early detection of the original lesion and of an impending recurrence, followed by intensive treatment, is of the utmost value in preventing stubborn recalcitrance

The factors favoring recurrence are unquestionably of two groups

1 The relatively uncontrollable ones, such as emotional disturbances, fatigue, and nervous tension
2 The easily controllable ones, such as smoking, dietary care, rest, exercise, and alcohol

They operate synergistically, but if the second group is always under control, the inroads of the first group are much less disastrous It should be mentioned that the diagnosis of ulcer recurrence must be as carefully made as that of the original lesion Not infrequently, because of the

ulcer history, other conditions are confused with it; indeed, often an irritable colon caused by magnesia used in the treatment of ulcer causes symptoms which are not sufficiently evaluated and are thought to be caused by ulcer recurrence. The possibility of recalcitrance after resection must be acknowledged preoperatively by the surgeon and a serious attempt must be made to prevent jejunal ulcer by a postoperative regimen.

Any discussion of the recalcitrant ulcer would be incomplete without recognition of the possibility of prevention of ulcer in its original or recurrent phase. Some among us believe that an attempt to prevent ulcer can be made with the detection of a tendency to hyperchlorhydria and spasm in the group of individuals who, we believe, later develop ulcer if nothing is done to protect them. Certainly an impending recurrence can be detected in the individual who has had a previous ulcer, by a rise in acid and increase in irritability, and such recurrence can be averted by immediate prophylactic measures.

In conclusion I would like to emphasize the following points: Since ulcer is a disabling systemic disease to which a certain group of human beings is susceptible, the earliest possible diagnosis should be made and the most intensive medical treatment used. A certain percentage of ulcers are recalcitrant but recalcitrance is very often in the patient himself and not in the ulcer. This can be overcome best by an early enlightenment of the patient concerning the nature of his disease. Gastric resection in the hands of experienced surgeons offers another opportunity for treatment of the recalcitrant ulcer but if surgery is necessary, postoperative recalcitrance can best be avoided if a careful regimen is used postoperatively.

YOUR DOCTOR

The war has not brought us any serious epidemics and no increase in child mortality. Yet 50,000 physicians are away with the armed forces. The home front medical job has been done by your doctor and all other doctors working overtime. It has been done by elderly physicians who have come out of retirement to help, and some of these have worked so far beyond their strength it has meant their death.

Every day, twenty-four hours a day, thousands upon thousands of doctors have labored without thought of self to pull the country through the war without a letdown of our high health standard, a standard which in spite of what some politicians would have us believe, is like our living standard, the highest in the world. Our doctors have not gone on strikes, they have worked day and night until exhausted. They have not taken vacations. Their hours on the job would not be permitted by union officials. They have not faltered in their attempt to help win the war and the peace after the war by keeping people at home in just as good health as possible. This has been a tremendous task for the doctors left with us. It has been a task greater than the people will ever know.

From now until peace comes, however, everybody will have to do as much as possible to help the doctors. They, like other human beings, must have a reasonable amount of sleep and rest. They cannot continue to be on the job night and day indefinitely. If they attempt to do so, they will break down themselves and we will have fewer doctors on whom to call. This means no person should call a doctor at night unless it is absolutely necessary. Call him in the daytime. Let him sleep as much as he can at night. He can then do a better job from breakfast time to bedtime.

Already far too many of our doctors have to start work early in the morning, continue with only enough time taken out to get a little something to eat until far into the night, and then, after getting to bed in an exhausted condition, are called out as soon as they get to sleep or after they have had but an hour or two of rest. No human being can keep up such a pace for long. It is truly remarkable that so many doctors have been able to do so for as long as they have.

Doctors should be called when needed. We cannot maintain a high standard of public health unless they are. They should not be called these days when they are not needed because this means they cannot give enough attention to those who need them badly.

Every day, your doctor works longer hours than you do. He is working while you work and he is working while you sleep. There are few, if any, other people who put in as many hours a day as he does. He cannot plan ahead to take a vacation or even a day off. When he feels he absolutely must get away to rest, somebody needs him. It is well to keep this in mind when you are tempted to call a doctor, but know in your own mind you do not really need him. There are not enough doctors to go around and if we are to have the services of one when we need him, we must share his services with others who also need him.

Also, it is well to keep in mind the truly marvelous service our doctors have rendered during this war period. We should keep it in mind when politicians say the whole procedure should be changed, that when doctors take their orders from politicians, the service will be better. These past three years have pretty well demonstrated that medical service could not be better than the doctors, unhampered by political interference, have made it. Yet, there is a bill pending in Congress which, if passed, would deprive the public of much it is getting now.—*Orange County Courier, Jan. 4, 1945*

THE ROLE OF QUININE IN COLDS, INFLUENZA, AND VIRUS PNEUMONIA

HENRY M FEINBLATT, M D , Brooklyn, New York

EACH decade brings many new contributions to therapy With the general interest aroused by their publicity, some of the old standbys are more or less pushed out of the picture The value of the older drugs is taken for granted by the older clinician, who feels that the facts should be just as obvious to his young assistant

The younger clinician, on the other hand, is impressed by the newer "miracle" drugs and often does not have the time or desire to learn about some of the older ones This situation is largely true of quinine

In the treatment of malaria, quinine continues to be our most valuable drug This value is so great that our government, notwithstanding the availability of synthetic substitutes, has asked physicians everywhere to restrict the wartime use of quinine to malaria Having in mind the bitter experience of Bataan and the Philippines, where lack of sufficient quinine proved a serious handicap in maintaining the health and activity of our soldiers, it has been decided very wisely that the precious reserves of this indispensable drug should be limited to its important medico-military use, namely, the prevention and treatment of malaria

It is to be hoped that Java, the world's principal source of cinchona and quinine, will soon be wrested from the enemy's possession Then quinine will again be freely available to American physicians not only for use in malaria but also in other conditions, such as the common cold and influenza, where it is believed to be of therapeutic value

Much has been written concerning the cause, prophylaxis, and therapy of the common cold, influenza, or grippe, as it is sometimes called, and the newer disease entity called virus pneumonia By the trial and error method, many theories have been proved practicalities and others have been dropped because with usage they did not live up to their promise

It seems to me, from the vantage of thirty years' experience, that in the therapy of these common ailments which attack and temporarily incapacitate so many of our population, a most helpful agent is very often overlooked I have found quinine of value in the treatment of these upper respiratory infections

In these conditions quinine acts as an antipyretic and analgesic, reduces the duration of the illness, diminishes the occurrence of complications, and may abort the illness itself if given early enough

Most textbooks on therapeutics mention that quinine has been used in the treatment of colds and influenza with beneficial results Some advocate its use as a prophylactic In this connection it is of interest to note that during the world wide epidemic of 1918 and 1919 numerous hospitals in southern Europe reported that influenza was practically unknown among the malarial patients who had been treated with quinine [1] Veilchenblau,[2] from his experience during this epidemic, stated that quinine is the only drug "in which a specific action can be perceived" I, too, believe that quinine exerts some degree of "specific action" against colds and influenza

Several recent American writers have commented on the value of quinine in the prophylaxis of influenza Barge,[3] on the basis of his experience in Florida, believes that, since quinine causes leukocytosis and increases the body defenses during the initial stage of influenza, it might be given as a prophylactic He further states that the evidence indicates that the incidence of influenza is much lower among persons taking quinine than among those not using the drug

In a study of 6,500 individuals taking quinine during the epidemic of January, 1941, as compared with 6,500 controls without the drug, Schnurman[4] found only one-fourth as many cases of influenza in the quinimized group as in the controls During the period of quinimization the number of cases waned, only to rise when the drug was discontinued

During a period of twenty two years, Showalter[5] prescribed quinine on numerous occasions in diseases of the respiratory tract, especially when the white-cell count was normal or below In his follow up study of these cases he was impressed with the increased white blood cell counts and marked improvement in the clinical condition of the patients Calling attention to the leukopenia caused by influenza and the leukocytosis produced by quinine, both in the early period of infection or use, Showalter suggested that the increase of white cells following quinine may have a great deal to do with the favorable clinical results

The cause of the common cold and influenza has long been a controversial issue On the basis of transmission experiments on apes and

humans, the cause of the common cold is now generally considered to be a virus. That the causative agent of influenza is a virus has been generally accepted since 1933, when Smith, Andrewes, and Laidlaw[6] succeeded in isolating a filtrable virus from patients with influenza by inoculating ferrets intranasally with filtrates of throat washings from patients with this disease. In 1940 Magill[7] and Francis[8] almost simultaneously demonstrated a second strain of virus causing influenza.

Within the past five years I have had under observation cases of nonspecific pneumonia which clinically resembled reported cases of primary atypical pneumonia, or "virus pneumonia," as it is now commonly called. In the treatment of ambulant and hospital patients, the symptomatic improvement and the rapidity of recovery of those treated with quinine were better than in untreated cases.

Although the disease simulates influenzal pneumonia in many respects, there is ample evidence to prove that it is a distinct disease entity. I am in agreement with Longcope's[9] view that, because of certain distinctive features of the disease, the causative agent may well be a filtrable virus. These features are its contagiousness, the long incubation period of ten to fourteen days, the inability to demonstrate by culture of the sputum or blood or by agglutination reactions that it is associated with any known pathogenic bacteria, and the peculiarity of the pathologic changes occurring in the lungs.

Attempts to isolate a virus from the throat-washings of a number of clinically typical cases in a wide variety of animals proved unsuccessful until 1940, when Weir and Horsfall[10] went to Jamaica in order to try to infect the mongoose. They were able to isolate a virus capable of producing pulmonary consolidation in these animals. It differed from other viruses known to cause infections of the respiratory tract in man. It has been impossible for workers in this country to reproduce these experiments, as it is illegal to import mongooses into the United States.

Although the virus nature of the disease is still speculative in the absence of confirmatory evidence, in view of the nature of the malady I am inclined to feel that it is essentially of virus origin.

The mechanism of the action that is exerted by quinine is still unknown. Three centuries of quinine therapy in malaria have not elucidated the action by which the plasmodium causing the disease is killed. The most popular concept is that quinine is a general protoplasmic poison and therefore toxic to unicellular organisms, as distinguished from groups of cells, as in the tissues. Use of quinine does not prevent a person from becoming infected with malarial plasmodia, but it does prevent the parasites from reaching a level of multiplication which will cause clinical symptoms of the disease.

One might speculate concerning the mechanism of the action of quinine in the treatment and prophylaxis of these respiratory infections of virus origin. The possibility remains that quinine acts on these viruses in a manner similar to its action on the malarial plasmodia.

In view of their specificity in pneumococcus pneumonia, the sulfa drugs have been given in numerous cases of virus pneumonia. As a matter of fact, it was failure of the sulfa drugs to produce their typical reaction in many cases that prompted the physician to search further for accurate diagnosis.

"The sulfonamide compounds," states Reimann,[11] "have not yet been shown to have any influence on influenza or other influenza-like pulmonary infections which have been prevalent in recent years, nor are they of value in pulmonary congestion, or in mixed infection of the lungs where bacteria susceptible to the sulfonamide compounds are not present."

In an experimental study, Coggeshall and Maier[12] tested various sulfonamides against influenza virus in white mice. They found that none of the drugs used was effective in delaying or preventing the development of the disease or in reducing the mortality of the infection.

The merits of the sulfa drugs are without doubt known to all, but their use should be limited to diseases caused by organisms which are susceptible to them. Because of their possible ill effects, they should not be used promiscuously and should be avoided in these virus infections in which they have no specific action.

I have routinely used 6 to 10 grains of quinine per day in these cases without observing any toxic effects. I have never had a case evidencing renal damage or degenerative changes of the blood.

Conclusions

1. In my experience quinine has proved to be a valuable therapeutic agent in the treatment of the common cold, influenza, and virus pneumonia. It acts as an antipyretic and analgesic, reduces the duration of the illness, prevents complications, and, if given early enough, may abort the infection.

2. The mechanism of the action of quinine in respiratory infections of virus origin is considered to be similar to its action upon the malaria plasmodia.

3. The sulfonamide compounds are not indicated for this group of diseases.

4. There have been no untoward effects with

use of quinine in dosage of from 6 to 10 grains daily

5 Because of the wartime shortage of quinine and its medico-military need for malaria therapy, the usage of quinine for common colds, influenza, and virus pneumonia may not be practical until after the war

THE EPIDEMIOLOGY OF CANCER

Concentration of control measures on those individuals or groups who have a greater than average chance of developing cancer because of exposure to one or more of a variety of predisposing factors or conditions was recommended recently by Dr Morton L Levin, assistant director of the Department's Division of Cancer Control, in an address before the Cooperative Cancer Control Committee, Pittsfield, Massachusetts

Speaking on "The Epidemiology of Cancer," Doctor Levin said that effort can be focused on certain elements of the population through education periodic examination, and early diagnosis to the same extent to which it is possible to predict the occurrence among them of cancer or certain forms of cancer To the individual himself a knowledge of certain aspects of cancer epidemiology, i e information regarding what groups are most likely to develop the disease and under what circumstances, may enable him to take preventive measures or steps that will lead to early diagnosis of the disease and the prevention of its more serious consequences

Dr Levin pointed out that with present knowledge it is impossible to say that any particular person or group will not have cancer It is known, however, that certain units of the population have a greater chance of developing this disease or some specific form of it, because of association with one or more of a number of factors such as

1 Exposure to various chemical and physical agents The substances and agents now known, or believed, to cause cancer in man include arsenic, tar, pitch and related products, certain amine dye compounds, roentgen rays, radium rays ultraviolet rays benzol, possibly asbestos, nickel carbonyl, and chromates Persons exposed to carcinogenic agents can be protected against such exposure and should be given frequent medical examinations even after they have left the occupation or activity concerned In this way cancer may be prevented or detected at an early and readily curable stage

2 "Precancerous" conditions Various diseases and abnormalities are frequently the forerunners of cancer For example, chronic cystic mastitis in women means increased liability to the development of breast cancer, polyps which are benign tumors, are prone to become malignant when they occur in the stomach, intestine, or rectum On the skin, the dry wrinkles often seen in farmers and sailors, sebaceous cysts or wens, scars resulting from burns, and a type of flat brown or gray wart seen in elderly people are the most common precancerous conditions There is also a relationship between syphilis and certain forms of cancer

3 Chronic irritation Various nonspecific types of irritation are sometimes productive of cancer For example, that caused by excessive smoking is frequently associated with cancer of the mouth and of the upper respiratory tract The brown skin mole may become malignant if it is subjected to mechanical irritation or to injury

4 Hereditary or familial factors With the exception of a few rare [illegible] hereditary, there is [illegible] of cancer is determined [illegible] a family in which cancer [illegible] of tumors does occur, or in which any type of cancer has occurred frequently, should take steps to avoid irritation of the site concerned, to remove precancerous conditions, and to act promptly should [illegible]

land, where increased mortality from certain forms of cancer in the lower economic groups has been studied most extensively, it has been found that among unskilled workers the cancer death rate is about twice that for the highest group of business man and professional workers The high mortality in the unskilled group is confined to cancer of the skin, lip, larynx, mouth, esophagus, and stomach In married women, classified according to the occupation of the husband, a similar though less marked relationship exists indicating that factors associated with general living conditions, rather than occupation, are responsible Broadly similar findings have been reported by various investigators in this country

[illegible] that present knowledge cancer among various use of exposure to these ors suggests the proba of cancer control measparticularly fruitful—

MYCOSIS FUNGOIDES: TWO UNUSUAL TYPES

One Presenting Leonine Facies; The Other, Parapsoriasis (?) in Patches for Thirty Years

E. WILLIAM ABRAMOWITZ, M.D., New York City, and BEN KANEE, M.D., Vancouver, Canada

(From the New York Skin and Cancer Unit, New York Post-Graduate Hospital and Medical School, Columbia University)

MYCOSIS fungoides, while not uncommon in dermatologic practice, always invites discussion. Like other types of the lymphoblastomas, the cause remains unknown. The clinical course of mycosis fungoides is chiefly cutaneous. Visceral participation may appear later in the course of the disease.

In brief, mycosis fungoides generally starts with a sharply limited eczematous lesion that is indistinguishable clinically and histologically from an ordinary dermatitis. Itching is common but may be absent. This is the so-called premycotic or first stage of the disease and may last for several months or longer. The eczematous eruption may disappear spontaneously or recede with topical medication or with superficial fractional x-ray therapy.

As time goes on, recurrence of the eczematous patches takes place. They become more and more infiltrated and assume various-sized figurative patterns. Histologic study of an excised lesion will reveal in many instances a characteristic polymorphous cellular infiltrate, some showing mitotic figures, the presence of a fine reticulum, and Pautrier's abscess in the epidermis. This is the second stage of the disease and may last for years without any apparent disturbance in health. The lesions come and go. X-ray therapy is usually of help.

The third and final stage of the disease is characterized by the development of granulomas that may reach the size of an orange or larger. Hence the other name, granuloma fungoides, which is given to this skin affection. The histologic picture is the same as that seen in the second stage but is more pronounced. The eruption is by now more generalized and the patient in time succumbs, either from exhaustion or from some intercurrent complication.

A few of the unusual features of mycosis fungoides that may be mentioned are the development of erythematous lesions instead of eczematous in the early stages of the disease; the absence of the first two stages and the development of granulomas from the start—mycosis fungoides d'emblée. Instances are reported in which some form of leukemia, lymphosarcoma, or Hodgkin's disease either developed during the course of or else appeared as a final phase of mycosis fungoides of the skin.

Reports of unusual cases of mycosis fungoides may be of help in recognizing others of an atypical nature. We are recording two such cases.

Case Reports

Case 1.—Mycosis fungoides: leonine facies—Mr. A. S., 46 years old, was born in Italy and has been in this country for thirty years. He was married and a clothes presser by occupation. He had bronchitis and malaria as a child, otherwise his health had been good.

About five years ago, a half-dollar-sized, red, scaly patch, which lasted about one month, appeared on the skin of the right side of his chest. One year later red scaly patches appeared on his legs with involvement of the face, chest, back, and arms, during the ensuing year. This persisted despite treatment by various dermatologists. During the past year swellings appeared on the face, scalp, and ears.

Description of the Skin Lesions: He was admitted to the New York Post-Graduate Hospital, service of Dr. I. Rosen, on May 28, 1943. The most conspicuous lesions were those present on the forehead, eyebrows, eyelids, and cheeks. These presented many marble-sized nodular infiltrations that threw the skin into deep folds, resulting in the appearance of a leonine facies. Closer inspection revealed filliform and papillomatous vegetations superimposed on the nodular infiltrations. The scalp also presented many nodules, most of these covered with crusts and scales. Much of the scalp was denuded of hair. There was a slight purulent and fetid discharge from the scalp and face that was particularly noticeable on pressure of the vegetating lesions on the forehead. The eyebrows and eyelashes were gone. The entire skin of the face, including the eyelids and ears, was thickened and lichenified (see Fig. 1).

The trunk showed numerous sharply limited dry and infiltrated plaques, some as large as the palm, all of a violet-red color. Nodular lesions were also present here and there. The skin of the genitals and adjacent areas was red, edematous, and weeping. A few nodular infiltrations were noticeable on the arms and legs. In addition, a dime-sized infiltrated and ulcerative lesion was present on the anterior surface of the left thigh. The palms and soles were of normal appearance.

Physical Examination: This revealed nothing of note except that the axillary, epitrochlear, and inguinal lymph glands were olive-sized and shotty.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

TABLE 1.—Blood Counts

Date 1943	Leukocyte Count	Polymorphonuclear Leukocytes	Lymphocytes	Erythrocyte Count	Hemoglobin Percentage	Platelets	Bleeding Time	Eosinophiles	Basophiles	Monocytes
5/29	15 050	72	9	4 070 000	60			16		3
6/7	18 000	72	13	4 100 000	63	350 000	1½ min Coagulation time 4½ min	11	1	3
6/16	22 300	76	10	4 270 000	66			9	1	4
6/22	22 750	76	13	3 880 000	60			10		1
7/24	13 600	72	6	4 080 000	72			9	1	12
8/5	10 000	79	6	3 800 000	72			5	2	8
8/13	7 700	72	24	4 250 000	78					4
9/11	15 550	69	14	4 740 000	81					7

Roentgenogram of Chest The report states that the heart was essentially normal The lungs showed an old puerile type hilus and central tubercle thickening and fibrocalcific deposits

Laboratory Data A twenty four hour urine specimen (May 29, 1943) was essentially normal Urea nitrogen was 8 5 mg per 100 cc , nonprotein nitrogen was 24 mg per 100 cc , urea nonprotein nitrogen, 34 mg per 100 cc , chlorides 510 mg per 100 cc , glucose 55 mg per 100 cc , cholesterol, 190 mg per 100 cc , vitamin C (blood plasma), 0 4 mg per 100 cc The cephalin flocculation test (Hangar) was 4 +, the icterus index was 4 6 units The sedimentation rate was 26 mm per hour, prothrombin clotting time, 26 5 per cent of normal (Russell viper venom), the blood Wassermann reaction was irregular, and the Kahn precipitation test was negative

Bone Marrow Smear (June 2 1943) Examined by Dr M N Richter The bone marrow smear showed numerous cells, a great majority of which were myelocytes of some variety There was no preponderance of any one type and there was no apparent defect in maturation Erythroblasts were present in somewhat diminished numbers Diagnosis myeloid hyperplasia of the bone marrow Chronic myeloid leukemia was not excluded Lymphatic and acute myeloid leukemia seemed unlikely

Histologic Studies Biopsy from lesion on forehead—On June 10, 1943 Dr Wilbert Sachs reported that at one edge of the section there were several dilated follicles the walls of which were broken There was considerable necrosis about these, with a tremendous cellular infiltration of small round cells polymorphonuclears, plasma cells, and numerous giant cells This portion was interpreted as folliculitis with a foreign body cell reaction

At the other edge of the section, there was a considerable cellular infiltration throughout the mid and upper cutis with dilated blood and lymph vessels The overlying epidermis at this point was irregularly acanthotic with parakeratosis of the surface layer The palisade layer was intact and there were no cavities within the epidermis The cellular infiltration was composed of small round cells, wandering connective tissue cells a few polymorphonuclear leukocytes, some multinucleated cells, and many plasma and epithelioid cells Between the cellular elements there was a fine reticulum There were some mitotic figures and grouping of cells The diagnosis was definitely that of mycosis fungoides Dr M N Richter, of the Department of Pathology, concurred in this diagnosis The microphotograph is omitted, because of the classic textbook microscopic appearance of the section

The histologic picture of the biopsies excluded leprosy Mycobacterium leprae was absent in stained section and also from the nasal smear

The report of the skin biopsy, dated April 18, 1942, taken at Johns Hopkins Hospital, where the patient had been under observation, was also of mycosis fungoides

Excised Right Axillary Lymph Gland On June 14, 1943, Dr A E Margulis, of the Department of Pathology, reported that the gross and histologic picture suggested an inflammatory and not a neoplastic process The diagnosis was dermatopathic lymphadenitis

Comments and Review of the Literature The patient received about 40 x ray treatments and numerous topical applications in other cities with little or no benefit While he was under our observation, x ray therapy (fractional unfiltered doses) to the face trunk, and extremities caused some involution of the lesions in all areas Itching subsided with the help of a calamine emulsion reinforced with menthol and phenol Wet dressings of potassium permanganate solution, the application of triple dyes and later a sulfathiazole cream to the face and scalp reduced the discharge The patient was sufficiently improved after three months to leave the hospital on August 15 for further treatment at the Skin and Cancer Unit He had to be readmitted to the hospital on December 18, 1943, because of a return of itching with weeping, scaly red patches on the genitals and the lower part of the trunk The facial appearance had not changed since he left the hospital except that there was little or no discharge and no odor

The blood count during the patient's first admission to the hospital showed a leukocytosis reaching a high of 22,750 The differential count, however, was in the normal range and smears of the bone marrow indicated that some form of leukemia was unlikely After his second admission to the hospital, his leukocyte count reached a high of 23,000 but the differential count was still in the normal proportions

The patient's stay in the hospital was characterized by recurrent weeping eczematous patches principally confined to the genitals and the lower part of

FIG. 1. Mr. A. S. (Case 1), showing the nodular infiltrations of the face, giving the appearance of a leonine facies; also the smaller vegetating lesions.

the trunk and thighs. Bouts of fever with general debility were also a feature. While the facial lesion appeared flattened, the eruption on his trunk became more elevated and seemed to be entering the fungoid or final stage of the disease.

The duration of the eruption, the severe itching, the eczematous recurrences, as well as the nodular appearance of the lesions of the trunk present in this patient, were classic for mycosis fungoides. The leonine facies was unusual. This was caused by the presence of nodular infiltrations on the face, throwing the skin into folds, as seen in leprosy. Papilloma-like elevations surmounted the nodules, giving them a raspberry appearance.

A review of the literature disclosed comparatively few reports of mycosis fungoides presenting a leonine facies.

The first report was made by Köbner in 1864.[1] A woman, 40 years old, had frambesia-like lesions not only on the face, but also on the trunk and extremities. A biopsy revealed the structure of mycosis fungoides. Demange,[2] in 1873–1874, reported a man, 60 years old, with tumors of the scalp and swelling of the skin of the face and eyelids, and also lesions of the body. Histologic study indicated the picture of mycosis fungoides or lymphadenoma. There was no mention, however, of a leonine facies. Galliard,[3] in 1882, observed a man, 37 years old, at the Hôpital Saint Louis with nodular lesions on the trunk. The skin on the face was thrown into deep folds and ridges, giving a leonine appearance. Ehrmann,[4] in 1913, presented a man with mycosis fungoides of the body with a leonine facies. There were no details as to age, biopsy, etc. Decrop and Salle,[5] in 1921, described facial lesions similar to those seen in the nodular type of leprosy in a man, 50 years old, an inhabitant of North Africa. The patient presented lesions characteristic of mycosis fungoides on the body. The biopsy confirmed the diagnosis of mycosis fungoides. Berggreen[6] reported a man, 59 years old, with mycosis fungoides, confirmed by biopsy, of twelve years' duration. In the last year of his disease nodular infiltrations of his face appeared, resulting in a leonine facies. Various standard textbooks on skin diseases give little or no description of this type of involvement of the face.

The leonine facies is encountered in the second stage of mycosis fungoides when infiltration of the skin lesions is developing and also in the terminal stage of the disease.

Parapsoriasis (?) in Patches

Parapsoriasis in patches was first described by Brocq[7] in 1897. The classic attributes of Brocq's disease briefly consist of brownish-red discrete and confluent noninfiltrated plaques that are more or less persistent and preferably located on the trunk and extremities. A fine furfuraceous scaling and/or lichenification may be observed in the plaques. Pruritus is usually absent. The general health remains good. Treatment is of little avail. The histologic picture of parapsoriasis in patches is often banal and is not accepted by all observers as decisive.

The incipient, especially the erythrodermic first stage of mycosis fungoides and the patch variety of Brocq's disease, may resemble each other both clinically and histologically. Wise and Rosen[8] and others have indicated the difficulties in differentiating these two diseases. Kiel,[9] in a critical review of the literature, discloses cases reported as classic parapsoriasis in patches that later turned out to be mycosis fungoides. He believes Brocq's parapsoriasis in patches is an incipient stage of mycosis fungoides. The following case report is an example of parapsoriasis in patches, both from the clinical and histologic standpoint, which later proved to be mycosis fungoides.

Case Report

*Case 2.**—A private patient, Mr. H. S., a merchant 54 years old, was born in England. His past history was irrelevant except for typhoid fever in 1914.

Description of Skin Lesions (November 1927): The right mammary area presented a sharply lim-

* Presented before the Manhattan Dermatological Society, October 15, 1942; published in Arch. Dermat. & Syph. 48: 427 (Oct.) 1943.

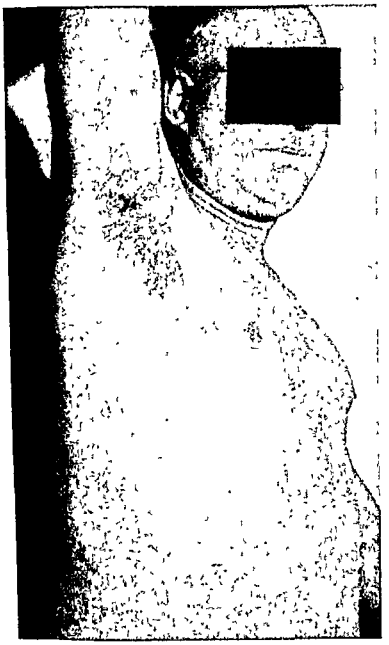

FIG. 2. Mr. H. S. (Case 2), showing the tanned quiescent lesion on the right mammary area. This and most of the patches on the trunk had been present for about thirty years. Later, the old eruption on the trunk, as well as some new areas that appeared, assumed a more reddened and slightly infiltered appearance. There were no subjective symptoms.

FIG 3. (Case 2) Sparse cellular infiltration of small round cells and wandering connective tissue cells. Slight disorganization of basal cell layer. Diagnosis: parapsoriasis. (Biopsy of right biceps area, April 26, 1929.) × 325.

ited, erythematous, slightly crusted dermatitis with some infiltration. This patch had been present for thirteen years without any discomfort, but had begun to itch recently and appeared more red than usual. Many light-brown scaly patches of various shapes and sizes covered his trunk and the inner sides of his arms. These did not itch nor did they annoy him in any other way. He said these had appeared in 1914 shortly after the eruption had developed on his chest.

Physical Examination (May 31, 1927) by Dr. H. O. Mosenthal: The patient was 42 pounds overweight (caused by overeating). The blood count was as follows: hemoglobin, 94 per cent; erythrocytes, 5,152,000; leukocytes, 6,505; polymorphonuclear leukocytes, 44 per cent; small mononuclears, 42 per cent; large mononuclears, 5 per cent; eosinophiles, 3 per cent; basophiles, 0 per cent; and transitionals, 1 per cent. There was an occasional faint trace of sugar in the urine with a somewhat lowered renal threshold. The blood-sugar curve was slightly below normal but it was believed no fundamental diabetes was present. The basal metabolic rate was 28 per cent. The rest of the laboratory and physical examination revealed nothing of note.

Clinical Course: The lesion on the right side of the chest receded under three fractional doses of unfiltered roentgen rays in 1927. No treatment was given to the eruption on the trunk.

He returned April 21, 1929, stating that the lesion on the chest had started to itch again and had become reddened. The chest lesion received x-ray therapy. Ultraviolet radiation was given to the brown patches on the body. He stopped treatment in July of the same year. The patch on his chest had turned brown and the itching had gone. There was no effect on the lesions of the body from the ultraviolet radiation therapy. No photograph was taken, but two biopsies were made—one from the eczematous lesion on the right chest and the other from a brown, flat patch on the right biceps area.

After an absence of thirteen years, during which time his skin gave him no trouble, he returned on July 31, 1942, because of a recurrence of redness and itching of the patch on the right side of his chest. The brown patches on his trunk and arms had become brown-red in color; no new lesions had appeared on the abdomen and upper and lower extremities. The photograph in Fig. 2 was taken in 1942. The appearance of these patches still conformed to what is commonly called parapsoriasis en plaques of Brocq.

Enlarged glands were palpable in the axillae and in the groins. His weight was about the same (195 pounds). Physical examination, roentgenologic study of the gallbladder and gastrointestinal tract, electrocardiogram, and blood counts revealed

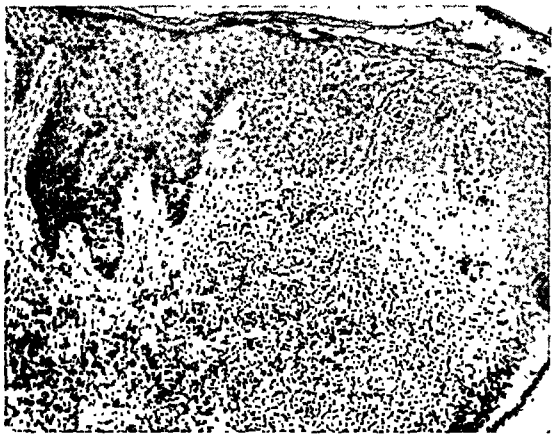

FIG. 4. (Case 2) Cellular infiltration in the cutis, composed of small round cells, wandering connective-tissue cells, polymorphonuclears, some plasma and epithelioid cells. Pautrier's abscess is present in the epidermis. Diagnosis: mycosis fungoides. × 275.

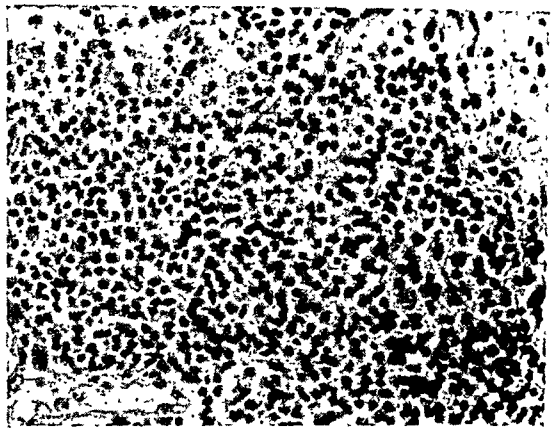

FIG. 5. (Case 2) High magnification of Fig. 4, showing the cytology. × 825.

nothing abnormal. He had some pain in the sacral area which was attributed to a chronic prostatitis.

He received subcutaneous injections of sodium arsenate (2 per cent solution), 5 to 10 minims three times a week. After twelve injections, he apparently became intolerant, so fractional doses of x-rays were again applied to the patch on the right side of the chest. Seborrheic warts present on his back for years were removed by electrodesiccation. He stopped treatment on September 1, 1942. The itching, redness, and scaling had gone from the patch on his right chest, leaving a tanned skin.

He returned on March 8, 1943. The chest lesion still appeared tanned and quiescent. However, new patches were appearing on his trunk and extremities. They were of the same nature as the old brown patches which had been present for about thirty years. The new as well as the old patches now showed a red tinge and felt slightly infiltrated. There was no itching or any other symptom. The axillary and inguinal glands felt smaller.

Sodium arsenate injections were again given, but as there was little improvement, therapy with unfiltered x-rays was now instituted to the affected areas of the body. The lesion on the chest did not require it. Treatment was discontinued June 30, 1943. All the patches on the trunk and extremities had become less conspicuous. The axillary and inguinal glands were barely palpable.

His last visit in March, 1944, showed the complete absence of all spots on his body excepting some pigmentation over the old eczematous area on the right side of his chest.

Blood Counts: Several blood counts taken during 1942, 1943, and 1944 were practically normal with the exception of a slight leukopenia.

Histologic Studies: Lesion on Right Breast (April 26, 1929)—Dr. D. L. Satenstein reported on the histology of the lesion. There was a general interstitial edema of the entire cutis and a parenchymatous edema of the deep cutis. The papillary bodies were quite uniformly swollen (broadened as well as somewhat lengthened). The vessels of the papillary bodies were dilated. The vessels of the subpapillary network were moderately dilated. There was diffuse cellular infiltration in this zone stretching clear across the entire specimen. The vessels of the midcutis were also moderately dilated. The epidermis was somewhat acanthotic in places. In spite of the changes in the papillary bodies, the suprapapillary portion of the epidermis was not relatively thinned. There was some parakeratosis, but for the great part, the granular layer was fairly well retained. Cellular infiltration was redominantly lymphocytic with a few connective-tissue cells present. Giant cells, plasma cells, or epithelioid cells were nowhere suggested. There was some basal-cell edema of the lower portion of the epidermis. There was no increase in fibroblasts. The vessel walls of the mid- and deep cutis were edematous (thickened). The characteristic arrangement of the infiltration, thinning of the suprapapillary portion of the epidermis looked for in the diagnosis of psoriasis, was wanting. The uniformity of the cellular infiltration was against mycosis fungoides. The lack of changes in the deeper cutis and epidermis ruled out chronic eczema. Therefore, parapsoriasis with secondary eczematous changes was suggested.

Lesion on Right Biceps Area (April 26, 1929)—The report was made by the late Dr. D. L. Satenstein, and later concurred in by Dr. W. Sachs. Dr. Sachs' description was as follows: Throughout the subepidermic region, there was a sparse cellular infiltration which was in part diffuse and in part focal. The vessels were slightly dilated. There was some interstitial edema, a little more pronounced in the subepidermic zone. The epidermis showed no change, except in two or three areas where there was edema of the lower portion. There was some disturbance, disorganization, and washing out of the basal cell margin and intercellular edema above it. Over these areas there were a few parakeratotic

cells The cellular infiltration was composed of small round cells and wandering connective-tissue cells The diagnosis was parapsoriasis (See Fig 3)

Biopsy from Lesion on Right Chest (August 6, 1944) —This report was made by the late Dr D L Satenstein and Dr W Sachs Another skin section was taken from the lesion on the right side of the chest The report was as follows Extending from the upper cutis to the epidermis was a tremendous diffuse, cellular infiltration The outlying lymphatic and blood vessels were dilated There was considerable interstitial edema present The overlying epidermis was irregularly acanthotic In some zones, the granular layer was retained and in other zones there was parakeratosis Toward the edge of the section, there were two small cavities within the epidermis containing the same cells as those found in the infiltration (Pautrier's abscess) The cellular infiltration was composed of small round cells, wandering connective-tissue cells, epithelioid cells, some polymorphonuclear leukocytes, and a few plasma cells There was a fine reticulum between the cellular elements There were mitotic figures and some grouping of nuclei Diagnosis mycosis fungoides (See Figs 4 and 5)

Comment Apparently this patient had mycosis fungoides from the start This was suspected in 1927 from the long standing eczematous lesion of the right chest, but it was not confirmed by the late Dr Satenstein, who had examined the first biopsy of the chest lesion in 1929 He believed the histologic picture suggested the presence of parapsoriasis with secondary eczematous changes The biopsy taken fr
to him
amined
men taken from the right chest in 1929 as a lymphoblastoma Dr Sachs, however, favored the diagnosis of mycosis fungoides Both were of the opinion that the specimen taken from the right arm in 1929 was still parapsoriasis

The brown plaques on the body had the classic appearance of the patch variety of parapsoriasis Histologically this was believed to fit in with that disease Like the eczematous patch on the right chest, finally proved to be mycosis fungoides, the so-called parapsoriasis on the rest of the body responded readily to x-ray therapy Even though no further biopsies were taken, it may be assumed that the pathologic process was mycosis fungoides in all the skin lesions

Summary and Conclusions

Mycosis fungoides may present a bizarre appearance in its various stages

A case is cited in this article in which a leonine facies developed which closely resembled that of nodular leprosy A review of the literature indicated comparatively few cases of this type

Another case is described in which a classic parapsoriasis in patches was present on the body for about thirty years together with an eczematous patch on the right side of the chest The appearance of the latter suggested mycosis fungoides The biopsy, however, failed to confirm this diagnosis and pointed to parapsoriasis, for this lesion as well as other lesions on the body Thirteen years later the clinical diagnosis of mycosis fungoides was confirmed

A favorable prognosis in cases of parapsoriasis in patches should be withheld, because of the possible transformation of such lesions into mycosis fungoides after many years

Discussion

Dr Marion B Sulzberger, *New York City*—It is, I believe, recognized that parapsoriasis en plaques does not usually yield to a few small doses of superficial x-ray, while the early lesions of mycosis fungoides do If, in a case which is clinically and histologically typical parapsoriasis en plaques, the lesions melt away under one to four fractional doses of superficial x-ray, this might well indicate that the eruption is mycosis fungoides The questions in my mind are the following

In typical cases, which all will agree to be clinically and microscopically parapsoriasis en plaques, are there not some which will respond well to x-ray therapy and some which will not? Are the former more likely to develop typical mycosis fungoides than are the latter? Must our prognosis in the x ray sensitive group be guarded or bad? May an invariably good prognosis be given in the x-ray-fast group?

These are questions which can be settled only by years and, above all, by administering x ray to all patients with parapsoriasis en plaques, keeping accurate records of the doses and results obtained, and by making arrangements for assembling in a central place all information on all cases of parapsoriasis en plaques which have been seen and treated, so that in the years to come any physician or pathologist encountering a case of mycosis fungoides or other "blastoma" may go to the central place of record and find out whether that particular case was ever diagnosed as parapsoriasis en plaques, and if so whether it was responsive or unresponsive to x-ray

Dr Wilbert Sachs, *New York*—Dr Abramowitz has described two very unusual cases These raise two interesting questions, one from the clinical and the other from the pathologic point of view

The first case is a clinical curiosity We do not

frequently see mycosis fungoides simulating the facies of leprosy. While it has been described, as Dr. Abramowitz stated, it is rare.

Lesions such as those seen in this patient are developing ones and not retrogressing. Pathologically one finds many large cells and at times mitotic figures; breaking up of cellular elements is not a feature of this type of lesion.

As far as the folliculitis is concerned, this is entirely secondary even to the clinical picture. In long-standing, itching eruptions in areas where the follicles are numerous and large, one would expect folliculitis to develop from time to time.

The second case interests me for two reasons. First, the development of mycosis fungoides in other dermatoses; second, the status of parapsoriasis as a dermatologic entity.

From time to time we hear of cases in which a patient had one disease which later turned into another. I do not believe in transformation of diseases. Either the patients have mycosis fungoides from the start or they develop it, irrelevant to the previous dermatosis. We read of psoriasis, seborrheic dermatitis, eczema, parapsoriasis, and perhaps others, lasting for many years, and then developing into mycosis fungoides. This is very understandable when one realizes that the clinical diagnosis depends in no small measure on the state of the epidermis, while the pathologic diagnosis, in the case of mycosis fungoides, depends entirely upon the cutis and its reaction. It is true that the epidermis in mycosis fungoides may be identical with the diseases mentioned, but not so for the cutis—this shows a definite picture from the start.

Therefore, I believe that this patient never had eczema, but mycosis fungoides. But the patient also had parapsoriasis.

I can understand why Dr. Abramowitz feels that the entire picture is that of mycosis fungoides. First, because such a diagnosis is established in this patient and second, because the parapsoriasis lesion as well as the others disappeared with x-ray therapy.

I do not believe that the contention is entirely valid. The pathologic picture was that of parapsoriasis and the clinical picture always remained that of parapsoriasis, while the other lesions showed clinical changes concomitant with the clinical picture of mycosis fungoides.

As far as the pathology of parapsoriasis goes, I believe that there is a definite entity known as parapsoriasis, which starts and remains as such. I also believe that there are many cases of so-called parapsoriasis with the clinical pictures of parapsoriasis which histopathologists cannot differentiate from this disease, but which in reality are mycosis fungoides. Perhaps in time with more knowledge these varieties will become distinguishable at the start, at least pathologically.

PHYSICAL RECONDITIONING HELPS CHEST SURGERY PATIENTS

A well-planned physical reconditioning program, started as soon as possible after the operation, contributes greatly to the success in the management of chest surgery patients, Col. John B. Grow, Maj. Omer M. Raines, and Maj. Ora L. Huddleston, (MC), AUS, declare in the *Journal* of the American Medical Association for December 23. Their report is based on results obtained in an Army hospital which showed that a high percentage of patients participating in the program return to military duty quickly in excellent physical condition.

"One of the major developments in the field of surgery during the present war," the three men say, "has been the general recognition of the value of a reconditioning program. The term 'reconditioning program' is a broad one and covers the care of the patient from the time of his operation until he is physically fit to return to his organization. The goal of this program may be simply stated as the restoration of the patient to a normal physical and mental state of health. . . . To be succcessful this program must be initiated as early in the convalescent period as possible and requires the close cooperation between the surgeon, the physical therapist, the occupational therapist, and the physician in charge of reconditioning. . . . ."

Twenty-two soldiers with chronic nontuberculous empyema (infection of the membranous lining of the lung) completed treatment during the period of the study which lasted twenty-one months. They were transferred to a reconditioning service as soon as they had been without fever for a sufficient period to take part in the program, usually from ten days to two weeks.

"As the patient's condition permits," the authors say, "breathing exercises, calisthenics, and outdoor drills and marches are engaged in. Vigorous physical activity has been found to be of definite benefit in hastening the obliteration of empyema and lung-abscess cavities. The usual experience is that by the time the empyema or lung-abscess cavity has disappeared the patient has been restored to his normal weight, stamina, and strength. . . . ."

Of the 22 patients, 18 were returned to duty and 4 were discharged from the service. Of 31 patients treated by surgical removal of a portion of the lung, 25 were returned to duty with an average of ten weeks of hospitalization following surgery. Their reconditioning program was started with breathing and shoulder exercises in the wards on the seventh postoperative day.

"Unfortunately," the three doctors say, "it is not possible to compare the results obtained before and after the initiation of the reconditioning program at this hospital, owing to the fact that the cases are not comparable and surgical technics have been changed during this period. However, the rapid response of this group of patients to the program, the excellent physical conditioning obtained, and the high percentage of cases returned to military duty have been striking. . . . ."—*A.M.A. News, Dec. 21, 1944*

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors The next report will appear in the April 1 issue and will concern ' Treatment of Poliomyelitis "

Choice of Sympathomimetic Amines

DR HARRY GOLD The conference today is on the subject of the choice of sympathomimetic amines Chemistry has only a limited place in these conferences, but I think it may help to bring the subject a bit closer to us if we have a look at the chemical structure of the group and the kind of variations that have been brought about in it

I have here an illustration of the structure of seven compounds which will serve to illustrate some of the points (Fig 1)

The skeleton of the group is the substance phenylethylamine, as pointed out by Barger and Dale in 1910 This is compound 1 It has two carbon atoms with an amino group on one and a phenyl group on the other The common drugs of the sympathomimetic series are substitution products of this simple compound

The substitution of a methyl group for one H on the first carbon atom gives rise to compound 2, which behaves differently from the first in several respects The vasopressor action of the new compound now lasts about twice as long, and the material is now rapidly absorbed from the gastrointestinal tract

Now look at compound 3 Here there has been added an OH to the phenyl group of compound 2 Pharmacologically, a great change has taken place Compound 2 has a strong stimulant action on the higher centers of the brain This is almost entirely lost in compound 3, as the result of the addition of the phenolic hydroxyl group Compound 2 is the well-known amphetamine, or benzedrine Compound 3 is paredrine In therapy paredrine is used chiefly for its peripheral actions, and benzedrine frequently for its central actions

When the OH group of paredrine (compound 3) is shifted from the phenyl carbon to the aliphatic carbon, making compound 4, a central action is restored, and the new drug, known as propadrine, acts in a manner similar to ephedrine, although it is stated to be somewhat less active on the centers than ephedrine

The substitution of a CH_3 group on the N of propadrine gives rise to one of the best-known members of the series, namely, ephedrine (compound 5) Pharmacologically, the resulting change is not great in this case, the vasopressor action of propadrine is somewhat greater and the central action somewhat less than for ephedrine There is indeed a question whether these two compounds are not interchangeable from the therapeutic standpoint

Now we come to another variation, seen in compound 6 It differs from ephedrine in that the methyl group on the first carbon is no longer there, and there is the catechol nucleus, namely, the benzene ring with the two OH groups This is the first member of the sympathomimetic group discovered, namely, epinephrine

Extraordinary pharmacologic changes take place if the OH group in the para position is removed This compound, 7, must be given in five times the dosage of epinephrine to produce the same rise in blood pressure The new drug rarely causes the ectopic cardiac rhythms seen after epinephrine therapy When raising the blood pressure, it slows the heart, while epinephrine accelerates it Its tendency to cause anxiety symptoms is much less than that of epinephrine This compound is neosynephrine

The order in which I have presented these few illustrations of the relation between chemical structure and action is for the purpose of simplicity only, and bears no relation to either their historical development or the manner in which the chemist deals with these materials in the synthesis of the particular compounds

In a few instances it is now possible, from the structure of the compound, to predict its behavior However, there are strict limitations to prediction because of the complexities of the pharmacologic change as the result of some of the chemical changes I have already referred to the introduction of a CH_3 group on the position of the first carbon atom By this change a two-carbon chain is converted into a three-carbon

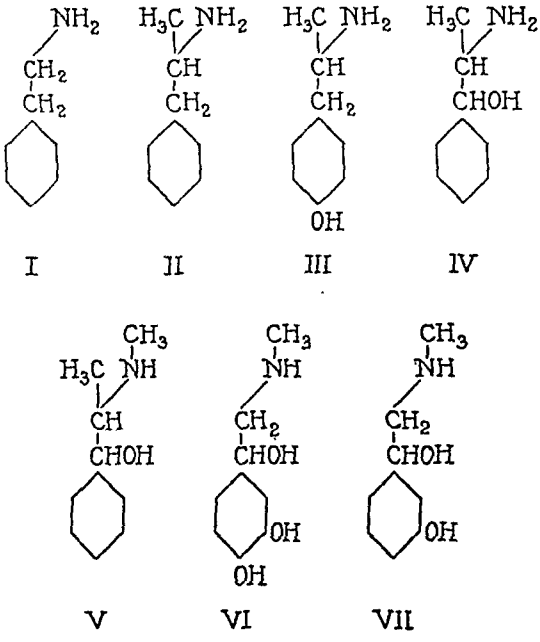

FIG. 1.

chain and the amino group is now on the second carbon rather than on the first carbon. Compounds of this character are well absorbed after oral administration. This applies to ephedrine, benzedrine, paredrine, and others. Compounds without this CH_3 group, such as epinephrine and neosynephrine, are not well absorbed when given orally. This difference is said to be due to the fact that deaminization, by which these compounds are detoxified, is accomplished with greater difficulty if the amino group is on the second carbon atom rather than on the first. This may not be the whole story, since there may be other ways in which these compounds are detoxified.

It is hard to know where to draw the line in the discussion of sympathomimetic compounds today. There are so many of them. Perhaps we should confine our remarks to those which are in most common use here, namely, epinephrine, ephedrine, amphetamine, neosynephrine, propadrine and paredrine. These materials are all put into the sympathomimetic group for the reason that they possess somewhat similar peripheral actions, actions which simulate those of the sympathetic or adrenergic nerves. Thus, they constrict some vessels (skin) and relax others (coronary). While they act on the smooth muscle of some vessels to cause constriction, they relax the smooth muscle of the bronchus and, under certain conditions, of the uterus. They tend to accelerate the heart and dilate the pupils.

Too much emphasis, however, must not be placed upon their similarities, and it is the pharmacologic differences which are of the greatest importance from the standpoint of therapy. The differences which are usually pointed out refer to central actions. Epinephrine and ephedrine cause anxiety and nervousness. With benzedrine in appropriately small doses, it is possible to obtain a different quality of central stimulation with more favorable alterations in the mood and the affect. Paredrine is almost devoid of central actions. However, I think one should point out that these compounds show important differences in the pattern of their peripheral actions as well. For example, epinephrine causes marked constriction of the vessels of the skin and produces pallor, while paredrine seems to cause no constriction of the vessels of the skin and this compound does not cause pallor. This difference in their action on the skin vessels makes epinephrine useful to delay the absorption of procaine for local anesthesia, while paredrine is of no value for this purpose. A comparison of neosynephrine and epinephrine gives another striking example of differences in the peripheral actions. You will recall that, from the chemical standpoint, neosynephrine differs from epinephrine only in the absence of the OH group in the para position. The results of a subcutaneous dose of the two compounds are so different that one is at a loss to see anything which they have in common. A subcutaneous injection of 1 mg. of epinephrine produces only a slight increase in systolic pressure, often a fall in diastolic pressure, increase in heart rate, increased cardiac output, and decreased circulation time. On the other hand, a subcutaneous injection of 5 mg. of neosynephrine causes a fairly marked rise of the blood pressure, slowing of the heart rate, decrease of the cardiac output, and may slightly prolong circulation time. Clearly, epinephrine places a burden on the heart with little rise of the systemic pressure, while neosynephrine may raise the blood pressure significantly without imposing a burden on the heart. An intramuscular injection of 10 mg. of paredrine may also raise the blood pressure by as much as 50 mm. and slow the heart rather than accelerate it.

The term "sympathomimetic" seems to have lost a good deal of its meaning as applied to the group of derivatives of phenylethylamine which have been synthesized.

Just a few words about the practical selection of members of this group in therapy: To what extent are they interchangeable, and which ones are best suited for the various purposes?

They all shrink mucous membranes when applied directly to them. The question of their

local irritant action in the nose and throat has received some attention Solutions of epinephrine are unstable and the sodium bisulfite preservative tends to be irritant Neosynephrine is relatively stable in alkaline solutions and may be sterilized by boiling There is the fact that epinephrine causes a secondary local vasodilatation, and is said on that account to be less desirable than some of the other members I am not certain that we have good evidence concerning the comparative actions of the various compounds in producing secondary disturbances in the nose and throat from protracted use The fact that these drugs tend to impair ciliary action in the respiratory passages has been used as a basis of comparison, but again I know of no satisfactory studies which establish one as preferable to another from this standpoint It takes about twenty times as much ephedrine as neosynephrine to produce the same rise of blood pressure, but for topical application to the nasal mucous membrane one usually recommends only four times as much ephedrine for the same effect (0 25 per cent solution of neosynephrine and 1 0 per cent solution of ephedrine) What is the meaning of this? When we observe differences in the results with these two solutions are we comparing strictly comparable concentrations? It is, of course, possible that ratios of potency which apply to their vasopressor actions do not apply to their action in constricting the blood vessels of mucous membranes by local application It is my impression that we are badly in need of some good experiments comparing the relative efficacy of the different members of the sympathomimetic group by local application to mucous membranes There is, of course, the point that paredrine and neosynephrine fail to produce central disturbances from the fraction which is absorbed, whereas ephedrine not infrequently gives rise to nervousness even after its local application Central nervous system stimulation is also sometimes seen with the use of the benzedrine inhaler Perhaps we may have some statement of preferences from rhinolaryngologists who may be here today

In regard to the field of allergy, especially for such conditions as bronchial asthma and angioneurotic edema, the contributions of the newer synthetic compounds seem to be relatively little The severe attack of bronchial asthma or angioneurotic edema or anaphylaxis still requires the dose of epinephrine Ephedrine provides some help in some of the milder cases Paredrine is of practically no value for this purpose

I wonder why that is? The attack of bronchial asthma is supposed to be due chiefly to the swelling of the bronchial mucous membranes and its relief by epinephrine presumably due chiefly to the shrinkage of the mucous membranes Yet the other members of the group which produce intense local constriction of mucous membranes seem to be of relatively slight effect in the case of bronchial asthma

DR MCKEEN CATTELL I am inclined to think that the antiallergic action of epinephrine is a specific property of the structure of epinephrine which may not be revealed in its pharmacodynamic action of either constricting vessels or relaxing bronchospasm

DR GOLD The new compounds have added a good deal to the therapy of certain kinds of circulatory disturbances There are many states in which vasomotor tone is seriously lowered This occurs in some stages of barbiturate poisoning It is seen in spinal anesthesia, in which the blood pressure frequently falls to as low as 75 mm of mercury It sometimes occurs in some phases of severe infection These are not true cases of shock There is need for an effective vasoconstrictor The action of epinephrine is too brief, too uncertain, and too disturbing The central stimulation by ephedrine is also a source of annoyance Paredrine and neosynephrine provide distinct improvements in the drugs available for raising the blood pressure by vasoconstriction

The central stimulant actions of amphetamine are also of considerable importance Its effect in allaying fatigue, reversing the depression by alcohol and barbiturates, and its role in the treatment of narcolepsy are some of the examples Here is a drug developed from the sympathomimetic group whose major contribution to therapy comes from its action on the higher centers rather than from any strictly sympathomimetic actions

DR CATTELL It would be worth while if we could have some statements from the different specialties in regard to the particular preparations which are employed, and if possible have the reason why Dr Kelley, you represent rhinolaryngology Will you say a few words?

DR SAMUEL F KELLEY I have used to some extent all the preparations mentioned here I have employed each drug sufficiently to obtain some impression as to the respective characteristic effects produced The therapeutic effect of a vasoconstrictor amine on the nasal mucous membrane is to provide ventilation and drainage of the nasal passages and sinuses and effect prompt relief from disagreeable symptoms The choice of such an agent is determined by its rapidity of action, duration of action, the nature and the duration of the aftereffects The ideal drug is one which develops its action rapidly, which has a prolonged vasoconstrictor effect and

a minimum of aftereffects. A number of factors, such as anatomic deformities, pathology, fatigue of the patient, tone of the vasomotor reflex, method of administration, and atmospheric conditions, result in individual variations in the effects of these agents.

Since any one of these drugs produces the desired vasoconstriction within two to fifteen minutes, the more important attributes which distinguish one from another are those of sustained action with a minimum of irritation and nasal aftercongestion.

I will take up epinephrine first. This drug is rapid in action, has a short period of action, and is characterized by various degrees of sneezing, watery nasal discharge, tearing of the eyes, and prolonged reaction. This reaction may persist from a few hours to a day or more. Shortly after leaving the office the patient may call the physician, complaining that the treatment has produced a severe head cold. A 1:100 solution of epinephrine is employed as a nasal and laryngeal spray for relaxing the bronchial musculature in certain cases of bronchial asthma. For local anesthesia about four to eight drops of 1:1,000 solution to the ounce of procaine is employed satisfactorily for nasal operations. A similar amount is employed in 5 to 10 per cent solution of cocaine for surface anesthesia. Caution is to be observed in its use, especially in the hypertensive or aged patient.

I used ephedrine extensively several years ago, but I seldom use it now, since the more recent amines have come into vogue. The immediate aftereffects and duration of reaction are less pronounced than for epinephrine. Its vasopressor effects and duration of action compare favorably with those of neosynephrine. It may be used in the form of a solution, or in oil as a spray, or as drops. When there is considerable discharge with swelling of the membrane occluding the ostia of the sinuses, the solution used as a spray or drops may prove more effectual than the inhalant because of a more general contact with the membranes. I do find that if ephedrine is used for a week or more the patient may complain of nervousness, restlessness, and perhaps insomnia. Some develop a local sensitivity to ephedrine. The nose becomes irritated, and the mucous membrane is blotched with small red and dry excoriations, especially on the anterior part of the inferior turbinate and in the dependent areas. By repeated applications more of the agent comes in contact with, and is retained longer in these dependent areas, and consequently there is a more prolonged vasoconstriction and irritating effect, which results in pathologic changes in the mucous membranes. Oral preparations are used with some measure of relief in cases of pollen asthma with nasal irritation and congestion.

I used benzedrine for a short time only. Its action is rapid, of relatively short duration, and the aftereffects of irritation and nasal congestion are rather marked and of prolonged duration. For this reason the patient may resort to frequent administration of the drug with short periods of relief and persistent irritation. This is a characteristic in various degree of all vasoconstrictors, and limitation of application should be insisted upon regardless of the amine used. If the nasal passages are not completely blocked the benzedrine inhaler may be conveniently employed after retiring at night or carried in the pocket for use when desired. The inhaler produces the same aftereffects as the drops or spray.

Paredrine solution is comparable in its local effect and after-reaction to that of benzedrine. I do not use it alone. I am using paredrine-sulfathiazole suspension in selected cases of nasal and sinus infections. Its action is rapid, sustained for two or three hours generally, and perhaps has some bacteriostatic effect. The reaction is less pronounced than for paredrine solution. I can offer no satisfactory explanation for this difference in effect, unless it is because it has a pH of 5.5 to 6.5, producing less hyperemia and irritation of the membranes. Being in the form of a suspension, it adheres to the membranes longer than the solution. I have restricted its home use in every case to not longer than three days in order to avoid nasal sensitivity to sulfathiazole. Directions are given to instill three to five drops in each nostril not oftener than every three hours and not more than four times in twenty-four hours. Since an important function of the nose is to expel foreign matter, bactericidal and bacteriostatic solutions are eliminated too rapidly to be of much value. The suspension can be visualized in the nose and pharynx for an hour or more following its application.

There are a number of aqueous solutions containing ephedrine and one of the sulfonamides. The same precautions should be taken in the use of these solutions to prevent developing sensitivity.

I used propadrine perhaps long enough to discover that its action and reaction were similar to that of benzedrine and paredrine.

Finally, I may say a few words about neosynephrine. While neosynephrine is by no means an ideal vasoconstrictor, I prefer its use in most cases to that of the other amines mentioned. It is employed as a spray, drops, and occasionally in the office by tampons. Its desired effect occurs within from two to fifteen minutes, and its action is sustained for two hours

or more. Fewer complaints of aftereffects, such as burning and nasal congestion, are made. In chronic conditions it may be used once or twice daily over a period of weeks with less tendency to develop local sensitivity. However, it isn't free of unpleasant effects. Neosynephrine may occasionally cause very disagreeable aftereffects upon its first application. On the other hand, more often it may be used for a considerable period without any complaint, and then suddenly cause irritation and nasal congestion to such a degree that it becomes necessary to discontinue its use.

If the drug is used frequently or indiscriminately over a protracted period, either a tissue tolerance may develop in which the vasoconstrictor response is weaker or more fleeting, or the contrary a chronic congestion or sensitivity may result.

In a case with chronic nasal congestion giving a history of extended use of a nasal spray or nose drops without evidence of an active sinusitis or other cause, one may suspect local sensitivity to the drug. Instructing the patient to discontinue all nasal medication may help solve the problem. In order to avoid prolonged and unnecessary treatment of the nose, and the consequences of these drugs, I write *"non repetatur"* on all such prescriptions. The patient is instructed to discontinue its use as soon as relief has been attained.

For mild acute nasal congestion, neosynephrine is used in a fine DeVilbiss spray. The atomizer is first primed by one compression of the bulb, and then four additional compressions are made, directing the spray at different angles with each compression. In this manner a more general distribution is made on the surface of nasal mucous membranes. If the ostia of the sinuses are occluded by swelling and discharge, drops prove more satisfactory when employed by the method of gravitation. The patient is instructed to recline on the back with the head hyperextended over the edge of a bed or couch. About eight drops (for the adult), or one-fourth of a standard medicine dropperful, of the neosynephrine is instilled into each nostril. The head must be so extended as to avoid an overflow into the nasopharynx. The patient is instructed to lie in this position for two minutes, and then sit up flexing the head and body forward for another minute. To remain five minutes or longer with the head hyperextended is very uncomfortable, seems to increase the congestion of the nasal membranes in some instances, and is rarely necessary.

Local reactions and aftereffects are still a source of disturbance in the case of the vasoconstrictors of the nasal mucous membranes, which are at present available. There is need for one with a minimum of these effects.

DR. GOLD: Dr. Kelley, is there any difference in the concentration of the solutions of various compounds which you use? Is it a 1 per cent solution of one drug or 0.5 per cent of another? Or just what do you do?

DR. KELLEY: I use 0.25 per cent neosynephrine solution. This is apparently an optimum concentration to obtain the desired and sustained action with a minimum of aftereffect and reaction. An increase in concentration above 0.25 per cent does not seem to increase the effectiveness of the drug. It is possible that the vasoconstrictor mechanism of the nasal mucosa has been stimulated to its maximum and a stronger solution fails to produce further vasoconstriction but increases the irritation. When the vasoconstrictor action has been spent the irritation from the higher concentration is more intense than that of the 0.25 per cent solution, resulting in more pronounced and prolonged nasal congestion.

DR. GOLD: In the case of ephedrine is it 1 per cent?

DR. KELLEY: No; 0.5 per cent of the aqueous solution, and 1 per cent in oil, not stronger. It is always best to use the weakest solution that will produce satisfactory vasoconstriction in order to reduce to a minimum the aftereffect and nasal congestion.

DR. CATTELL: I think we need to go on to some of the other fields. Dr. McLean, is there anything from the standpoint of the use of these agents in the eye?

DR. JOHN MCLEAN: There is not very much to be said. Most of the drugs of this group have been used in ophthalmology. They are used topically and principally for two purposes, for superficial vasoconstriction, and for mydriasis. It is commonly thought that epinephrine produces no mydriasis, and in the usual strength in the normal eye that is correct, but in greater concentrations in the normal eye, when introduced topically, it does produce mydriasis.

I have no personal experience with propadrine hydrochloride. I have had some with the others. They have all been used for the same purpose. For example, one uses ephedrine sulfate in 4 or 5 per cent solution for simple mydriasis without cycloplegia. Neosynephrine is used in 0.25 to 0.5 per cent solution for the same result. It comes on somewhat faster. It goes without saying that mydriasis without cycloplegia is in many instances quite important.

There is one other point which should be mentioned. It creeps into the literature and creeps further into commercial advertising. It is alleged that all, or almost all of these drugs are

synergistic with the atropine group in producing cycloplegia. I do not believe there is any sound evidence to that effect, and there are now very careful experiments which support my view. Proper controls in the experiments demonstrate there is no synergistic effect in cycloplegia, but only a summative effect of the two drugs in the mydriasis which goes with it. There is the erroneous conclusion that because the pupil is opened wider and more rapidly, therefore cycloplegia will be more complete

Statements have been made that a combination of one of these amines and a cycloplegic not only gives effective cycloplegia for refraction, but also wears off more rapidly than the cycloplegic used alone. The experiments on which this statement is based are misleading. For example, one dose of homatropine plus one dose of paredrine or benzedrine were compared with a course of six doses of homatropine. If the single dose of homatropine is used either with or without the alleged synergist, the cycloplegic effect and the recovery time are the same. In either instance, the recovery time is shorter than with the six doses of homatropine.

Neosynephrine is a popular one of the group now, not so much because of any special pharmacologic properties as because of the convenient way it is put up commercially, and the wider range of solutions which are available.

Dr. Gold: You haven't noticed any difference in local irritant actions in the eye after ephedrine, neosynephrine, paredrine, and benzedrine?

Dr. McLean: Not appreciably.

Dr. Cattell: Are you not using neosynephrine in much lower concentration than ephedrine? You mentioned that point.

Dr. McLean: Ephedrine is not used any more because its action is slower and it requires stronger solution. If you use these drugs in physiologically equivalent strengths you get about the same results.

Mr. Donald Clarke: Might I ask what the purpose of the 10 per cent neosynephrine is?

Dr. McLean: The 10 per cent neosynephrine solution applied locally in the eye is a very strong pupillary dilator by muscle stimulation, yet it is very readily overcome by the ordinary miotics. We use the 10 per cent neosynephrine in two specific types of cases. In one group are those in which strong mechanical obstruction is to be overcome, for example, an iritis with an adhesion between the iris and lens which we would like to break forcibly by nonsurgical means. The other application is as a preparatory drug in certain types of ocular operations in which it is important to get maximal dilatation of the pupil during the operation and prompt miosis afterwards.

Dr. Gold: Would you say that these needs are met by neosynephrine, but not by the others? I am still trying to find out whether there are any important differences between the compounds.

Dr. McLean: No. It probably can be done adequately with the others, but we haven't readily available strengths of the others comparable to 10 per cent neosynephrine. One can do just about the same thing with about 2 per cent epinephrine, which is considerably stronger than the ordinary epinephrine which is available. Neosynephrine is just more conveniently supplied.

Dr. Cattell: Dr. Foot, would you say something about the use of these compounds in anesthesia?

Dr. Ellen B. Foot: Of these drugs the one which the anesthetist uses the most is ephedrine, that being the most commonly known and an easily available drug for maintaining blood pressure during spinal anesthesia. It has, however, many disadvantages, and many of us are using paredrine and neosynephrine in preference to ephedrine to maintain the blood pressure for spinal anesthesia.

There are two kinds of central stimulation as opposed to peripheral stimulation which is seen with these drugs. That probably is not a strictly correct way of saying it, but expresses the clinical picture well. When ephedrine is given to a patient with spinal anesthesia, who has a vasomotor block from the fifth thoracic segment on down, the chief reason that ephedrine is given is to elevate the blood pressure through increasing the cardiac output. Its peripheral effect is necessarily limited to the arms, neck, and head. In other words, it is largely increase in the work of the heart which elevates the patient's blood pressure and restores the circulation. That is perfectly all right in an individual who may be regarded as a good risk, but in a patient with a poor myocardium the result may not be an increase in cardiac output but instead cardiac failure and an even worse situation than the original. The increased cardiac output is what I call central circulatory stimulation as opposed to the effect on the periphery of the vascular system. The second type of central effect is stimulation of the medullary vasomotor centers.

Dr. Gold: Perhaps one ought to state that you base your statement that the vasopressor action of ephedrine is largely the result of cardiac stimulation, on the evidence presented by Starr and his collaborators, to the effect that a dose of ephedrine which increases the blood pressure decreases the effective peripheral resistance. This would indicate that vasoconstriction is not an important factor in the blood pressure rise. We may also assume that when you speak of the

peripheral constriction being limited to the arms, the neck, and the head in a patient under spinal anesthesia in whom there is vasomotor block from the fifth thoracic segment down, you accept the view that ephedrine vasoconstriction is not a direct action on the muscle cells, but results indirectly from its blocking an enzyme which inactivates epinephrine. In such a case, the anesthetic block of the vasomotor control becomes in effect a kind of denervation of the corresponding blood vessels which would accordingly show little constriction with ephedrine.

DR. FOOT: With paredrine and neosynephrine one characteristically gets an unchanged pulse or a bradycardia, and there is much less possibility of having an untoward arrhythmia or decompensation. The pressor effect is a very gratifying one from a practical standpoint. I prefer paredrine to neosynephrine because of its longer duration. A patient under continuous spinal anesthesia for a period of two or three hours may require neosynephrine in small doses every fifteen or twenty minutes. Each successive dose is just as effective as the previous one, but the patient, aware of getting so many hypodermic injections, begins to think that maybe he is not as well as he ought to be, and he is aroused repeatedly from his sedation, which might otherwise allow him to drowse throughout the operation. The effect of paredrine, on the other hand, lasts satisfactorily from one to three hours after a single dose.

The doses which I have found effective are from 3 to 5 mg. of neosynephrine. That seems to be ample to restore blood pressure depressed by spinal anesthesia, and is also sufficient as a prophylactic dose prior to the administration of the spinal anesthetic drug. With paredrine the dose range is 5 to 8 mg. for both prophylactic and therapeutic use for controlling the hypotension of spinal anesthesia. The dose of ephedrine is of the order of 50 mg. but a prophylactic dose of 35 mg. is often adequate.

We have used benzedrine as a pressor drug in connection with spinal anesthesia, but because of the central nervous system stimulation it is unsatisfactory. The patients become too wide awake and the preanesthetic sedation is counteracted so that although the blood pressure is well maintained, the patient is too aware of the operating-room activities to be entirely happy.

STUDENT: Do you ever use paredrine for elevating the blood pressure when it goes down during or after the operation under pentothal anesthesia?

DR. FOOT: With the intravenous barbiturates we find benzedrine very useful in bringing about a prompt return of orientation. The typical patient recovering from pentothal anesthesia usually wakens as from a quiet sleep, and comes to a full realization of where he is and what is going on; but an occasional patient will wake up in a state of inebriation. He is uncooperative and is disoriented as to time, place, and person. Benzedrine is dramatically effective in removing this type of recovery reaction. In a patient who has had pentothal for the application of traction to a fractured extremity, for example, it is quite important to have the patient cooperative as soon as he recovers and not to have him toss around in bed or try to get up and walk across the ward. Prompt orientation on awakening is also important when pentothal is used for air encephalography, so that patients can cooperate for the taking of x-ray pictures after the air encephalogram is complete.

DR. MCLEAN: By what route do you give benzedrine?

DR. FOOT: The intravenous route. In adults 10 mg. is often enough. If not effective within ten minutes, the dose can be repeated intravenously without any ill effect. There may be a mild blood-pressure rise, so that in the markedly hypertensive patient I would advise giving the second dose intramuscularly or subcutaneously. A few anesthetists have tried giving benzedrine by mouth prior to pentothal anesthesia with the idea that it takes twenty to thirty minutes for the benzedrine to be absorbed, so that just about the time the patient needs to be wakened he will be absorbing the benzedrine. That does not work at all. It is more apt to make it necessary to give the patient a larger total dose of pentothal, with the end result of an even longer recovery period. We do not as a rule need any pressor drugs in connection with the intravenous barbiturate anesthesia. It is very rare to see any blood pressure depression with pentothal anesthesia unless massive doses are given rapidly. Ordinarily the blood pressure is maintained at the preoperative level or rises slightly because of shallow ventilation and CO_2 retention.

STUDENT: How do you give paredrine in the case of intravenous pentothal, or don't you use it?

DR. FOOT: It is not useful for pentothal anesthesia as paredrine does not have the cerebral effect of benzedrine.

SAME STUDENT: During operation is it ever desirable to raise the blood pressure without central effects, and in that case would you use paredrine rather than benzedrine?

DR. FOOT: That is the case during spinal anesthesia. With inhalation anesthesia it is more rational to treat hypotension with fluids, blood, or plasma, instead of with pressor drugs. The patient with surgical shock has already failed to profit from his own physiologic attempts at compensation by vasoconstriction and increased cardiac output. Giving a pressor drug un-

der such circumstances is said to constitute "whipping a tired horse." The only justifiable reason for using pressor drugs in this situation is that they may increase peripheral circulation for a brief period and facilitate finding veins suitable for vensipuncture and the administration of blood and plama.

One word of caution, and that is that epinephrine and some of the anesthetic agents are incompatible, in that ventricular fibrillation can occur very readily when there is a relatively large amount of circulating epinephrine during cyclopropane, chloroform, or ethyl-chloride anesthesia. Therefore, patients who are scheduled for operation under local anesthesia, who may require a supplement, and in whom the supplement will probably be cyclopropane, chloroform, or ethyl chloride, should not receive procaine or cocaine solution to which epinephrine has been added.

DR. CATTELL: There is one important subject, I am sorry to say, we did not get to, and that is the question of the use of these substances by the psychiatrists. I don't see anyone from that department here.

STUDENT: I would like to ask Dr. Gold this question: For a patient who has just had a sympathectomy, whose blood pressure prior to operation was 200/120, which after operation goes to 90/60 as the result of loss of vasomotor tone, what drug would you use and approximately how much?

DR. GOLD: Paredrine or neosynephrine would be preferable to any of the others we discussed because central stimulation is either absent or negligible. An intramuscular dose of 5 mg. of neosynephrine or 10 mg. of paredrine should suffice. The paredrine is often effective in 20 to 40-mg. doses given by mouth. The effects come on in about ten minutes or less. The doses may be repeated as necessary or increased if necessary.

Benzedrine has been used for the treatment of a condition involving an essentially similar problem, namely, orthostatic hypotension. Here the stimulant action on the higher centers is sometimes found to be desirable, although wakefulness may be a drawback. There is some successful experience with paredrine in orthostatic hypotension. It failed to produce the psychic lift. Rather large doses were used orally, as high as 400 mg. a day.

DR. FOOT: At the Massachusetts General Hospital, Dr. Smithwick used both paredrine and neosynephrine, sometimes one and sometimes the other, in sympathectomy cases, only at the second stage with the section of the second side.

He used them prophylactically on the operating table prior to the section of the sympathetic chain. Moderate doses of paredrine and neosynephrine were very effective.

Summary

DR. GOLD: Several of the more popular members of the sympathomimetic amines were under discussion in today's conference, namely, epinephrine, ephedrine, paredrine, propadrine, benzedrine, and neosynephrine. In this group small chemical changes in structure often result in marked pharmacologic differences. They differ with respect to the presence or absence of central stimulant action and the quality of the central effects, also with respect to the pattern of their peripheral actions on the blood vessels and the heart. The discussion emphasized some of the points of significance in the choice of preparation for therapeutic use, especially in the field of rhinolaryngology, ophthalmology, and anesthesia.

They are all effective vasoconstrictors when applied locally to the mucous membranes of the nose in from 0.25 to 1.0 per cent solutions. Preference was expressed for neosynephrine although local irritation and chronic congestion resulting from their prolonged use is a source of disturbance in the case of all of them. While these drugs are frequently used in combination with sulfathiazole in the form of nasal drops, it should be mentioned that the practice is not without danger because of the possibility of sensitization to the sulfa-drug, which may preclude its subsequent use for conditions in which it may be essential.

Epinephrine is still the drug of choice in the severe attack of bronchial asthma or angioneurotic edema.

There seems to be little choice between them for use in the eye as topical vasoconstrictors or mydriatics. Neosynephrine was preferred here chiefly because of the convenience of the wide range of solutions which are available. It was pointed out that the notion that these agents, used with members of the atropine group, promote cycloplegia of shorter duration, is incorrect and based upon badly controlled experiments.

Paredrine is here the drug of choice for restoring the blood pressure in spinal anesthesia. The absence of central stimulation is an important feature.

This drug and also neosynephrine are useful for maintaining the blood pressure in other states of vasomotor depression, although of little value in secondary shock. The special central stimulant action of benzedrine is applied in controlling the confusional state which occurs during recovery from pentothal anesthesia. There was

not sufficient time to do more than to touch on the several other uses of the central stimulant action of benzedrine

There is obvious need for more systematic clinical comparisons than there are at present to provide a sounder basis for therapeutic selection among these compounds in some of the fields in which they are put to use

---

MEDICAL WRITING

One would not suspect from reading current medical literature that the field of medical writing has, at least in the past, contained some of the best craftsmen the English language has had Perhaps the highest peak to which the use of classical English has attained was reached by Sir Thomas Browne There has been a serious, lamentable decline since then Medical men can still write on nonmedical subjects—Maugham, Cronin, Céline, Munthe, Osler, Cushing, and, before them, Weir Mitchell and Holmes, for a few But when they take up a medical topic, they forget such splendid traditions and even the simple rules and meanings they learned in school

Some of those writing today can still be read without shuddering, but few, with the exception of some English writers, are read with the same pleasure that Peabody, Allbutt, Fitz, Janeway, and Thayer of the generation just past and a considerable body of men before them command A guide to medical writing is pertinent and such a handbook, *Medical Writing*, by James H Dempster, should do a good deal to elevate the present low state of grammar and construction, if not of vocabulary —if it is read

Certainly, if medical men go to the trouble (how many of them really do?) of putting findings on paper with the presumable purpose of having others read them, they should consider it worth while to use language and sentence structure which are not only intelligible but are at the same time at least not unpleasant or uncomfortable for the reader It takes real genius to abuse the English language

[illegible]

ence, and most articles published make an attempt to appear so, at least the innumerable charts, graphs, and formulas are probably meant to convey that impression (upon close scrutiny most of them fail to produce any impression other than one of confusion and bewilderment) Scientific medical writing should be clear and convey meaning—and writing on the art of medicine could even be entertaining

To point out all the weaknesses in present medical writing would require a compilation almost as extensive as Mencken's on the American language The most glaring examples are those which have to do with qualifications of "positive," "negative, and "normal," "essentially normal," "essentially positive or negative" Besides the lack of meaning of "essentially," can you really modify absolutes? Granted that there are no absolutes, then why use the terms at all? The whole subject of modifiers needs searching discussion And the complete lack of [illegible]'t there any otl There is a sor n, which is usually not medical and not quite always English

Case reports are particularly badly handled They are really simple narratives, but most of them read like blank verse by T S Eliot It is a pleasure to read some of the case records of Bright, Addison, Corrigan, Sydenham, and Graves And I venture the opinion that there is as much scientifically valuable content in the writings of Thomas Lewis, Mackenzie, Cushing, and A F Hurst as in any medical writing extant, and yet how easily and simply and pleasurably it is read

Semantics has been recently rediscovered by Stuart Chase It is, by definition, the study of the changes in the meaning of words in the way of special[illegible] is amplified by Korzyb[illegible]e accurate use of wor[illegible]rents Stuart Chase [illegible] analyzes the use of words as symbols The exercise is very entertaining Most language, as it is spoken and written, is just "blab", whereas, with proper study of referents and reference it should actually convey ideas exactly and accurately from one person to another What is meant by democracy, fascism, capitalism, economics, money? What is meant by immunity, allergy, myocarditis, nephrosis, gastritis? The rule seems to be *what*, *when*, and *where* with regard to a [illegible] tion Do two [illegible] al-ways mea[illegible] Well then, wh[illegible] implicit that the meaning in each case is clear Everyone knows that diplomatic language employs ambiguity to hide meaning, but surely one medical man communicating his thought to others need not follow the devious circumlocutions of statecraft The most accurate language of all is mathematical, [illegible]atters of human rela-[illegible]s mathematical terms, [illegible]at is at all clear in the [illegible] should be capable of expression in understandable symbols

All of which means that present-day medical writing is generally done in a very sloppy manner It is stereotyped as to use of words, abounding in clichés, tautologies, and inaccurate modifiers There is no style to it, whereas there is no reason why there should not be The meanings are often obscure, in many cases, because of muddy thinking to begin with and carelessness in denoting by context or direct statement the referents for the word symbols used

After all, there is too much medical writing, as indeed there is a plethora of all writing, but one [illegible] published by Bruce, is recommended as an aid to better writing And a reading of Stuart Chase might lead to an avoidance of glib and meaningless generalities —*James B Carey, in Bulletin, Hennepin County Medical Society*

der such circumstances is said to constitute "whipping a tired horse." The only justifiable reason for using pressor drugs in this situation is that they may increase peripheral circulation for a brief period and facilitate finding veins suitable for vensipuncture and the administration of blood and plama.

One word of caution, and that is that epinephrine and some of the anesthetic agents are incompatible, in that ventricular fibrillation can occur very readily when there is a relatively large amount of circulating epinephrine during cyclopropane, chloroform, or ethyl-chloride anesthesia. Therefore, patients who are scheduled for operation under local anesthesia, who may require a supplement, and in whom the supplement will probably be cyclopropane, chloroform, or ethyl chloride, should not receive procaine or cocaine solution to which epinephrine has been added.

DR. CATTELL: There is one important subject, I am sorry to say, we did not get to, and that is the question of the use of these substances by the psychiatrists. I don't see anyone from that department here.

STUDENT: I would like to ask Dr. Gold this question: For a patient who has just had a sympathectomy, whose blood pressure prior to operation was 200/120, which after operation goes to 90/60 as the result of loss of vasomotor tone, what drug would you use and approximately how much?

DR. GOLD: Paredrine or neosynephrine would be preferable to any of the others we discussed because central stimulation is either absent or negligible. An intramuscular dose of 5 mg. of neosynephrine or 10 mg. of paredrine should suffice. The paredrine is often effective in 20 to 40-mg. doses given by mouth. The effects come on in about ten minutes or less. The doses may be repeated as necessary or increased if necessary.

Benzedrine has been used for the treatment of a condition involving an essentially similar problem, namely, orthostatic hypotension. Here the stimulant action on the higher centers is sometimes found to be desirable, although wakefulness may be a drawback. There is some successful experience with paredrine in orthostatic hypotension. It failed to produce the psychic lift. Rather large doses were used orally, as high as 400 mg. a day.

DR. FOOT: At the Massachusetts General Hospital, Dr. Smithwick used both paredrine and neosynephrine, sometimes one and sometimes the other, in sympathectomy cases, only at the second stage with the section of the second side.

He used them prophylactically on the operating table prior to the section of the sympathetic chain. Moderate doses of paredrine and neosynephrine were very effective.

Summary

DR. GOLD: Several of the more popular members of the sympathomimetic amines were under discussion in today's conference, namely, epinephrine, ephedrine, paredrine, propadrine, benzedrine, and neosynephrine. In this group small chemical changes in structure often result in marked pharmacologic differences. They differ with respect to the presence or absence of central stimulant action and the quality of the central effects, also with respect to the pattern of their peripheral actions on the blood vessels and the heart. The discussion emphasized some of the points of significance in the choice of preparation for therapeutic use, especially in the field of rhinolaryngology, ophthalmology, and anesthesia.

They are all effective vasoconstrictors when applied locally to the mucous membranes of the nose in from 0.25 to 1.0 per cent solutions. Preference was expressed for neosynephrine although local irritation and chronic congestion resulting from their prolonged use is a source of disturbance in the case of all of them. While these drugs are frequently used in combination with sulfathiazole in the form of nasal drops, it should be mentioned that the practice is not without danger because of the possibility of sensitization to the sulfa-drug, which may preclude its subsequent use for conditions in which it may be essential.

Epinephrine is still the drug of choice in the severe attack of bronchial asthma or angioneurotic edema.

There seems to be little choice between them for use in the eye as topical vasoconstrictors or mydriatics. Neosynephrine was preferred here chiefly because of the convenience of the wide range of solutions which are available. It was pointed out that the notion that these agents, used with members of the atropine group, promote cycloplegia of shorter duration, is incorrect and based upon badly controlled experiments.

Paredrine is here the drug of choice for restoring the blood pressure in spinal anesthesia. The absence of central stimulation is an important feature.

This drug and also neosynephrine are useful for maintaining the blood pressure in other states of vasomotor depression, although of little value in secondary shock. The special central stimulant action of benzedrine is applied in controlling the confusional state which occurs during recovery from pentothal anesthesia. There was

not sufficient time to do more than to touch on the several other uses of the central stimulant action of benzedrine.

There is obvious need for more systematic clinical comparisons than there are at present to provide a sounder basis for therapeutic selection among these compounds in some of the fields in which they are put to use.

MEDICAL WRITING

One would not suspect from reading current medical literature that the field of medical writing has, at least in the [illegible] subjects—Mayo, Cronin, Céline, Munthe, Osler, Cushing, and, before them, Weir Mitchell and Holmes, for a few. But when they take up a medical topic, they forget such splendid traditions and even the simple rules and meanings they learned in school.

Some of those writing today can still be read without shuddering; but few, with the exception of some English writers, are read with the same pleasure that Peabody, Allbutt, Fitz, Janeway, and Thayer of the generation just past and a considerable body of men before them command. A guide to medical [illegible] such a handb[illegible]pster, should state of grammar and construction, if not of vocabulary—if it is read.

Certainly, if medical men go to the trouble (how many of them really do?) of putting findings on paper with the presumable purpose of having others read them, they should consider it worth while to use language and sentence structure which are not only intelligible but are at the same time at least not unpleasant or uncomfortable for the reader. It takes real genius to abuse the English language. There are no Faulkners, Hemingways, and Dos Passos' at present [illegible] journals—even h cavalier [illegible]part a science, and most articles published make an attempt to appear so; at least the innumerable charts, graphs, and formulas are probably meant to convey that impression (upon close scrutiny most of them fail to produce any impression other than one of confusion and bewilderment). Scientific medical writing should be clear and convey meaning—and writing on the art of medicine could even be entertaining.

To point out all the weaknesses in present medical writing would require a compilation almost as extensive as Mencken's on the American language. The most glaring examples are those which have to do with qualifications of "positive," "negative," and "normal," "essentially normal," "essentially positive or negative." Besides the lack of meaning of "essentially," can you really modify absolutes? Granted that there are no absolutes, then why use the terms at all? The whole subject of modifiers needs searching discussion. And the complete lack of originality in modifying words! Aren't there any other English words besides "marked"? There is a sort of medical English being written, which is usually not medical and not quite always English.

Case reports are particularly badly handled. They are really simple narratives, but most of them read like blank verse by T. S. Eliot. It is a pleasure to read some of the case records of Bright, Addison, Corrigan, Sydenham, and Graves. And I venture the opinion that there is as much scientifically valuable content in the writings of Thomas Lewis, Mackenzie, Cushing, and A. F. Hurst as in any medical writing extant, and yet how easily and simply and pleasurably it is read.

Semantics has been recently rediscovered by Stuart Chase. It is, by definition, the study of the changes in the meaning of words in the way of specialization or generalization; or, as amplified by Korzybski, Ogden, and Richards, the accurate use of words with regard to their referents. Stuart Chase ("The Tyranny of Words") analyzes the use of words as symbols. The exercise is very entertaining. Most language, as it is spoken and written, is just "blab"; whereas, with proper study of referents and reference it should actually convey ideas exactly and accurately from one person to another. What is meant by democracy, fascism, capitalism, economics, money? What is meant by immunity, allergy, myocarditis, nephrosis, gastritis? The rule seems to be *what*, *when*, and *where* with regard to any generality like truth, or inflammation. Do two individuals writing about metabolism always mean the same *thing*? Manifestly not! Well then, why cannot the referents be so explicit or implicit that the meaning in each case is clear. Everyone knows that diplomatic language employs ambiguity to hide meaning; but surely one medical man communicating his thought to others need not follow the devious circumlocutions of statecraft. The most accurate language of all is mathematical; and, unfortunately, few matters of human relationship can be reduced to mathematical terms, but any thought or idea that is at all clear in the mind of the author thereof should be capable of expression in understandable symbols.

All of which means that present-day medical writing is generally done in a very sloppy manner. It is stereotyped as to use of words, abounding in clichés, tautologies, and inaccurate modifiers. There is no style to it, whereas there is no reason why there should not [illegible] are often obscure, in many case[illegible] to begin with and [illegible] context or direct statement the [illegible] word symbols used.

After all, there is too much medical writing, as indeed there is a plethora of all writing; but one [illegible] to make a contribution to the overburdened litera[illegible] The last [illegible] Democr[illegible] as an aid to better writing. And a reading of Stuart Chase might lead to an avoidance of glib and meaningless generalities.—*James B. Carey, in Bulletin, [illegible] County Medical*

Special Article

THE PLACE OF THE MEDICAL PRACTITIONER IN THE SELECTIVE SERVICE SYSTEM

JOHN A. P. MILLET, M.D., New York City

(Chairman, Emergency Committee of Neuropsychiatric Societies of New York City, and Director, The Lake George Foundation, Diamond Point, New York)

THE successful operation of the Selective Service System and the induction stations presupposes the readiness of the civilian medical practitioner to volunteer his services as medical examiner, or to respond to the call of the county society in the event that a shortage of medical examiners threatens the effective operation of the induction process. This fact signifies that the medical profession is an integral part of our system of national mobilization to meet the emergency. While the response of the civilian practitioners to this added responsibility has been enthusiastic and whole-hearted, it has not everywhere been accompanied by a thorough understanding of wherein their greatest usefulness lies.

As medical examiner to the local boards, as a member of a Medical Advisory Board, or as one of the specialists serving at the induction stations, the civilian practitioner has the opportunity to participate directly in the program of national mobilization, and in one or more of these roles a large majority of the civilian profession has found, in addition to this opportunity for service, deep satisfaction in a new field of experience.

There are, however, other aspects of a physician's contribution which are becoming of increasing importance as the period of active induction draws toward its close and the number of rejectees and discharged soldiers rises toward an eventual maximum.

One highly significant aspect of every physician's role in relation to Selective Service is that of interpreting to the draftee, to his family, and to the community the responsibility of the individual for service and the reasons for possible rejection. In carrying this role of interpreter of Selective Service requirements, the medical practitioner, through his personal and civic contacts, has an unique opportunity for aiding in the maintenance of civilian morale. Such a role has always been associated with the medical profession in peacetime, and should now be emphasized as one of its greatest opportunities on the home front.

No matter what role he may play with respect to an individual candidate, he has always the opportunity and responsibility for building up morale and for dissipating anxiety, whether that anxiety be due to possible acceptance, or to possible rejection. Unusual anxiety in either direction, or preoccupation with the results of any single phase of the examination may be regarded as presumptive evidence of emotional instability, and should be noted for the benefit of the neuropsychiatric examiner.

The importance of the neuropsychiatric phase of the examination at the induction center cannot be too strongly stressed. There is often a tendency among physicians to discount such complaints as "nervousness" or "indigestion," or such evidences of dangerous instability as overindulgence in alcohol, irresponsibility in employment, and repeated brushes with the law. Too often are heard such comments as "The Army will make a man of him," or "Let him try pulling that stuff when he is in the Navy." While it is doubtless true that in some instances adventurous individuals who have come into conflict with a law-abiding community in peacetime may make excellent soldiers, it is equally true that similar conduct may indicate deviation from the norm of sufficient gravity to render a candidate most undesirable in the role of soldier.

In determining physical norms there is far less difficulty for the practitioner than in establishing mental norms. It is certainly obvious that if hearing is seriously impaired the defect can be measured and evaluated from the standpoint of suitability for Army service. The question of how the deafness came about is of secondary importance. With neuropsychiatric problems, on the other hand, barring clear signs of organic nervous disease, the history behind the symptom is of as great importance as the symptom itself, and frequently gives the best clue to its importance. Only specialists who are trained to such careful history-taking, and who from long experience can put their fingers quickly on significant evidences of mental illness or emotional instability should be entrusted with these difficult evaluations.

There is no possible doubt that the chance of overlooking a poor neuropsychiatric risk is

greater than that of overlooking a poor physical risk

In the time at the disposal of the neuro psychiatric examiner it is not possible for him to secure all the evidence which he needs to feel sure about doubtful cases On the other hand, if he has had a rich clinical experience, he will undoubtedly spot many bad risks which would escape the notice of less skilled observers, or which would have been passed up as eccentrics, or as being 'hopped on themselves" and therefore good subjects for 'having all that nonsense knocked out of them "

Furthermore, not only is it easier to determine and evaluate physical pathology than psychopathology, but, once the candidate has been accepted, and is being run through the mill, physical overstrain will be more readily recognized and more correctly evaluated than emotional or nervous strain, or than certain evidences of psychopathic personality which may cause all kinds of trouble to everyone later Training is so intensive in many instances that physical weakness soon leads to physical breakdown Mental illness or a latent susceptibility to mental and nervous breakdowns, however, may well elude observation once the wheels of the training mill are set in motion It is true that many neuropsychiatric misfits are weeded out prior to the six months' limit after which they can claim service-connected disability, and that many nervous breakdowns or psychosomatic illnesses appear during the first week after induction It is unfortunately true, however, that just as latent instability may elude detection by others, so it may not be fully appreciated by the individual himself until he is near the breaking point Thus may come during the first week or month of his service, or may not appear until he is on a transport, or undergoing preinvasion training, or, finally, is engaged in active combat

If a selectee is rejected at the induction station for neuropsychiatric reasons, or is discharged after a brief term of service, he frequently is placed in a most embarrassing situation at home He cannot give any satisfactory explanation He may be believed to be a malingerer, or to have shirked his duty, or else to be a "nut," and may find difficulty in securing employment or re-establishing "face" Sufferers from "nerves' who look perfectly healthy rarely are sympathetically regarded by their neighbors, and even by their own family physicians

If we consider, on the other hand, the lot of the man rejected or discharged for physical infirmities, while he may be relieved or disappointed as the case may be, he does not have to hang his head nor give some vague explanation He can describe his disability without embarrassment, and receive the sympathy of his neighbors and their help in getting himself re-established

The general practitioner has always been regarded as something more than a healer Like the minister, the lawyer, or the sheriff, he is expected to be one of the leaders in the community and it is to his everlasting credit that with rare exceptions he takes particular pride in the confidence which his community places in him In these critical years his opportunities and his responsibilities are greater than ever before There is hardly a family in the country whose lives and fortunes are not in some way threatened or changed by the course of the war Those families which have to face the problem of a father, son, or husband returning with some degree of disability, whether it be great or small, physical or emotional, will need more than ever the technical skill and the enlightened sympathy of their family physician Already the quantity of discharged men has reached beyond the million and a half mark Of these, some 44 per cent have been discharged as neuropsychiatric casualties For the reasons above stated it is likely that the families of these men will be more bewildered by their situation than is the case of those of men with medical discharges in other categories It is imperative, therefore, that every general practitioner acquaint himself with the problems which these men have to face, and with the attitudes that need to be built up among the members of their families There have, unfortunately been a number of regrettable and misinformed magazine articles which have only served to increase the misunderstanding and prejudices in regard to the situation Furthermore, the earlier use of such technical medical diagnoses as "Psychoneurosis" in connection with certificates of discharge has tended to increase the anxiety of the neuropsychiatric dischargee, to confuse and frighten his family, and to prejudice potential employers against him

Here, then, is one type of situation in which the family physician can exercise a new and important function, that of sustaining the morale of rejected selectees or dischargees, and of educating their communities to the understanding that unsuitability for military service does not necessarily indicate unfitness for civilian life, nor any strange abnormality of make-up

Fortunately, in contrast to some badly conceived and widely publicized statements in the lay press and magazines, there is now a growing literature on the subject which emanates from reputable professional sources The National Committee for Mental Hygiene and the New York State Committee for Mental Hygiene can supply a suitable reading list for physicians who wish to become better acquainted with the

problems involved. There is, however, another aspect of the physician's relation to his community which should be given further emphasis. As physician to a draft board he naturally will be interested in those veterans whose fitness for induction was first determined by his own examination. It will now be his privilege, and should be felt as his responsibility, to see to it that upon his return with a medical disability each man be given whatever medical care is indicated.

There will be many doubts in the minds of the veterans and of their families as to the suitability of medical or surgical care that has been given or that is being recommended. These doubts are likely to be particularly disturbing in the field of neuropsychiatric disabilities. Some of these patients will need hospitalization, but will resist the idea with violence. Their resistance may be bolstered up by the refusal of their families to accept the situation. Others will crave the protection of a Veterans Administration Hospital, when their greater need is to be helped to a successful readjustment in the community. It will take a great deal of tact, wisdom, and skill to see all these men through to the best possible finish. Where there are inadequate local facilities for the outpatient type of neuropsychiatric care the physicians in the community should arouse the leading citizens to an awareness of the problem, and sponsor the formation of a citizens' committee to establish a mental hygiene clinic. When there are not sufficient funds in the community to make this possible the leading physicians should organize themselves into an advisory group for the purpose of making the best possible use of whatever professional resources are available. Whatever may be the problem in any given community, the New York State Committee for Mental Hygiene stands ready to offer advice and suggestions, and to assist in a local educational campaign.

Many men discharged with neuropsychiatric disabilities have experienced no difficulty in civilian life because there has been sufficient freedom of movement and choice to allow them to find a niche wherein their sensitivities are not handicaps, or sometimes may even be assets, and wherein they may function effectively. These have included such sensitivities as inability to work in high places, inability to function in crowds, or alone, or in closed places, maladjustments to authority, tendencies to unusual forms of sex expression, a tendency to cruelty, or its reverse, the inability to kill anything, or even to handle a gun. Some of these conditions are detectable in advance and can be dealt with during the process of selection. Some of them, such as fear of heights and gun-shyness, can be trained out of the person if they are not too deeply ingrained. With some persons, however, these sensitivities persist as distinct handicaps and necessitate discharge.

These subclinical handicaps to military service are generally not known or detectable by the community, or even the Selective Service Board. But when a man is rejected by the induction board or discharged from the Army for such cause, he is apt to be surrounded by suspicion—suspicion of malingering, or of having political influence. When such a man returns home with the diagnosis of psychoneurosis, he may meet prejudice on the part of the community and industry that sometimes prevents his serving to the fullest extent as a part of our manpower, and as a result may become lost to the war effort as well as to himself. A circular issued some time ago by a toolmaking industry calling for men to train as toolmakers, specifically excepted those discharged for psychoneurosis, although in such work many psychoneurotics could function superbly. Recently a psychiatric clinic in St. Louis made a special effort to place in a machine shop one such man discharged from the Army. He proved to be the best of the fifty men employed, with the result that this clinic has since been called upon by his shop to recommend other candidates.

Such an experience both proves the moral and adorns the tale which this article aims to relate. To make it possible for such a demonstration to become the rule rather than the exception requires widespread understanding of the whole problem on the part of the medical profession, who will then be in a position to re-educate prospective employers and the general public with respect to the needs and rights of the draftee or dischargee who is returned to his community for some neuropsychiatric reason.

Without the assistance of this better understanding these men may continue to find themselves embarrassed and resentful on their return to their own communities. They may continue to have one disappointment after another in seeking re-employment; and in many instances the conflicts thus engendered may end in antisocial attitudes and acts, or in escape into the backwaters of neurosis and chronic invalidism. Here, indeed, is a challenge which every medical man should be proud to accept as a further contribution to the war effort and to the cause of science and humanity.

The process of screening has been greatly improved by the addition of medical field agents to the local draft boards, and by the wider use of neuropsychiatrists attached to the Medical Advisory Boards, as well as by the recent directive in relation to the use of approved psychologic tests. Full credit should be given to the officers

in charge of the Induction Center at the Grand Central Palace for their initiative and for their cooperative attitude toward those of their civilian colleagues who have been active in the development of these tests and in urging other improvements in screening procedures From the outset, Col Samuel J Kopetzky (Medical Director of Selective Service for New York City) has shown the keenest interest in these matters, and has initiated or sponsored many projects that have led to these improvements

While the screening technic in New York City is therefore now a model for other large communities, there still remains the problem of a shortage of neuropsychiatrists in the rural or semirural districts Where no experienced neuropsychiatrists are available their functions are frequently exercised by young men in the State Service, or by less skillful men who are glad to be able to earn the regular, if modest, stipend paid by the Army for their services Such a state of affairs in many instances has resulted in complete failure of the procedures designed to eliminate neuropsychiatric risks from the Service, and highlights the paucity of well-trained neuropsychiatrists in the less densely populated areas

At the Neuropsychiatric Clinic operated in Glens Falls by the Lake George Foundation one young man came in at the suggestion of his family physician because he was badly alarmed at the wording on his rejection slip "Psychoneurosis, severe, irremediable" While he had no idea what the term psychoneurosis meant, he knew very well what the adjectives implied This young man had apparently been rejected because an inexperienced neuropsychiatric examiner had decided that he must be very neurotic, since he had admitted hesitation to marry his girl-friend prior to induction, on the ground that he already had the sole responsibility for supporting his mother Since he was not neurotic, though quite sensitive, he accepted the reassurance given at the clinic with relief, and subsequently found employment which was sufficiently remunerative to enable him to marry Here was an example of prompt action on the home front which forestalled a possible serious break in individual morale

It is hard to determine what would be the best term to use in classifying neuropsychiatric discharges, or in the endorsement of such papers as might have to be presented to the general public We may confidently expect that the abandonment of technical medical diagnoses on discharge certificates and the substitution of less frightening terms will eliminate at least one obstacle in the path of the veteran's readjustment

The medical profession cannot be taken to task for its failure to do good screening Its members have cooperated enthusiastically with the Selective Service System Shortage in neuropsychiatric personnel and slowness of recognition by the authorities of the importance of neuropsychiatric disabilities have been responsible for much suffering that might have been avoided These mistakes have now been remedied so far as it is humanly possible to do so Furthermore, the present enlightened policies of the armed services in regard to attempting a readjustment of men with more or less serious nervous reactions within the framework of army or navy life, rather than discharging them immediately to civilian life, should go far in reducing the number and variety of neuropsychiatric discharges Much of the credit for these new policies belongs to the Surgeon General, Maj Gen Norman T Kirk, and to his Chief Neuropsychiatric Consultant, Col William C Menninger, who, in addition to his unceasing efforts to improve the treatment of neuropsychiatric cases in the Army, never loses an opportunity of reminding the civilian physician of his responsibility toward the disabled veteran and his family

As physicians, then, we must take up this challenge Probably the most important service that the civilian neuropsychiatrist can give at this time is educational Owing to the very recent recognition of the need for proper teaching, in the medical schools, of clinical psychiatry and psychosomatic medicine, there are few practitioners of medicine above the age of 45 who have the benefit of medical education as to the significance of these fields of inquiry in the evaluation and treatment of human functional disorders The influence of the great eras of Virchow and Pasteur still dominates our middle-aged medical thought and leaves little freedom for the understanding and acceptance of basically new viewpoints Furthermore, the busy practitioner must needs stick to what he already knows and has little time to weigh the values of these new disciplines, nor to read the voluminous literature in which observations and theoretic constructions pertinent to them are recorded The younger members of the profession, who have been fully exposed to these new scientific data while still in medical school, are for the most part in uniform, so that we must depend on a handful of well-trained specialists to make known to their fellow practitioners in civilian life such parts of these new concepts, at least, as have an important bearing on the process of selecting men whose stability will be assured in the face of any but the most extravagant type of danger, and on the nature of the problems which they may present if discharged as neuropsychiatric casualties

The Emergency Committee of Neuropsychiatric Societies of New York has for some time

devoted much of its energies to this purpose. One article written for the Committee by Dr. Earl H. Adams[1] attempted to outline for the benefit of the general practitioner the principal points to look out for in the detection of emotional instability or functional nervous disorders.

Another pamphlet on the returning veteran written by Dr. Emeline P. Hayward, in collaboration with me,[2] is shortly to go to press under the sponsorship of the New York State Committee for Mental Hygiene. The Committee has also collaborated with the Federal Council of Churches in the preparation of material for all those who may be called upon to give advice and counsel to the returning veteran.[3]

There is no excuse in these days for ignorance of these topics. To acquire what knowledge is available does not require a vast amount of reading. The problem for the medical practitioner is rather that he be prepared to meet his responsibility. It is a regrettable fact that New York State is the only state in the union in which no provision has been made in the program of the State Bureau of Rehabilitation for the inclusion of neuropsychiatric casualties among those veterans entitled to state aid in their rehabilitation. This strange omission calls for the wholehearted support of the medical profession in calling for an enabling act of the Legislature which would set up such services under the aegis of the State Department of Mental Hygiene or the State Board of Social Welfare. The State Department of Education under which the Bureau of Rehabilitation functions has no personnel or experience which would qualify it for the effective administration of such a program.

Finally, we come to the problem of the overlapping functions and enthusiasms of the various organizations which are attempting to help the veteran in his readjustment. Someone recently described the situation in these words: "It looks to me as though it was getting to be a scramble for the customer." The physician who has been in close touch with the workings of the Selective Service System, and who is properly informed as to the resources in his community, can save "the customer" and his family a lot of unnecessary heartaches. He can become the one person best fitted to light the veteran through the darkness and confusion of his period of readjustment. Many of those whose powers of adjustment have been temporarily shattered are having real problems in accepting what opportunities there are. Others are able to get along because the employment situation is still favorable, and because they want to forget their troubles rather than to seek aid in their solution. What will happen to many of these men when the employment situation becomes less favorable, and the period of obligation toward them on the part of employers is no longer in effect, is still imponderable, but that there will be serious problems and disabling anxieties for many is certain.

The specter of unemployment may soon be hovering above the social horizon. Lessons learned from successes, failures, and problems in the mobilization of our manpower for war may offer some valuable guideposts in effecting a successful redistribution of this same manpower in the peacetime community. The principle of selection according to fitness for the job should play a leading part in overall planning to meet this staggering situation, and the physician must be prepared to use his experience, knowledge, and influence in promoting an understanding of the problem among his clientele and in the community at large.

VIRUS DISEASE FROM PIGEONS MAY BE A CAUSE OF SPORADIC ATYPICAL PNEUMONIA

In view of the high percentage of pigeons in the United States infected with ornithosis, a disease similar to psittacosis which is contracted from psittacine birds, such as parrots, and since countless individuals are daily exposed to this potential reservoir of infection, it is probable that the virus of ornithosis may be responsible for many sporadic cases of primary atypical pneumonia which pass unrecognized, three physicians declare in the *Journal* of the American Medical Association for December 23.

Lt. David C. Levinson, (MC), AUS, Lt. John Gibbs, (MC), AUS, and Joseph T. Beardwood, Jr, M.D., of Philadelphia, report 6 sporadic cases of ornithosis the diagnosis of which was confirmed by laboratory tests. A history of direct contact with pigeons was obtained in 2 cases and in the others there was daily exposure to pigeons in the immediate vicinity of the homes. They point out that it is known that infection may occur through the inhalation of the infected excreta of pigeons blown about as dust.

Six of fourteen pigeons captured in Philadelphia were found to have positive tests for ornithosis.—*A.M.A. News, Dec. 15, 1944*

A MILD CASE OF TETANUS—CASE REPORT

ALAN R ANDERSON, M D , and GEORGE A NEWTON, M D , Freeport, New York

TETANUS ordinarily is a disease characterized by severe symptoms and a high mortality rate According to authorities reporting on a large number of patients, this rate in treated cases may be anywhere from 27 to 60 per cent It has been noted[1] that a short incubation period (up to six days) without prophylaxis may lead to a disease having a mortality of 90 per cent, if, however, the incubation period is over ten days, a lower mortality of about 50 per cent may be expected

To our knowledge it is not generally appreciated that tetanus can be a mild disease, and can present difficulties in diagnosis because of this mildness Especially in the prodromal stages, regardless of whether the succeeding disease is mild or severe, a number of diagnoses may be entertained before the physician arrives at the correct one of tetanus There may be pain and spasm in the muscles of the face and neck, and those of deglutition, there may be pain on swallowing without objective signs of a sore throat, there may be pain in the back with a mild degree of stiffness simulating myositis or one of the rheumatic diseases According to one authority, about 2 per cent of the cases are treated by extraction of a tooth or palliatively for disease of the nose and throat Actually, a few cases of tetanus have been subjected to an abdominal operation because of the tremendous rigidity of the abdominal muscles!

Case Report

We are reporting a case of tetanus seen in the summer of 1943 in a farmer of 70, because of (1) the difficulty of convincing ourselves that it really was a case of tetanus, (2) the mildness of the course of the disease, (3) *the absence of a history of injury* and (4) the thought that other physicians in rural communities might encounter cases of similar mildness

H B, a farmer of 70, came to the office of one of us on the evening of July 14, 1943, complaining of a stiff neck which had been present for three days He gave no history of injury did not have a fever, showed considerable spasm of the neck muscles, was told he had a stiff neck, and was advised to use heat at home for relief On July 17, he
ton
the
cause of the continued stiff neck and rigidity of the spinal and abdominal muscles, it was felt that a lumbar puncture should be made On this day he was walking about the room, holding himself very rigid, and when forced
considerable difficulty
position The spinal
mal pressure, and no increase in the cellular content
From July 19 to 22 there was no improvement If anything, the rigidity of the neck and back muscles increased, and because of stiffness of the jaws it become more difficult to feed him The diagnosis of tetanus had been seriously considered by both of us, certainly as early as July 17, when he first complained of difficulty in swallowing But the general good condition of the patient, the absence of any history of injury, and the absence of frank convulsive seizures persuaded us to ascribe his symptoms to some type of myositis involving chiefly the back and neck muscles One of us, on July 19 or 20, talked the problem over with a well-known neurologist, and he expressed the opinion that a man who had had tetanus for ten days would more than likely be dead! Despite this opinion, we were forced to conclude in the next few days that the patient really did have tetanus No myositis could be so persistent or involve so many groups of muscles

He was admitted to Meadowbrook Hospital on July 22 The blood pressure was 130/80, the temperature was recorded as 101 5 F on the day of admission 101 F on July 23, and normal thereafter *The pulse was recorded as high as 90,* but more often 75 to 80 The respirations were from 22 on admission to 20 on discharge, and at times were recorded as 25 During the first few days at the hospital, he had for the first time slight tonic contractures of the entire back when an attempt was made to move him in bed He was given 20,000 units of tetanus antitoxin on the first day, and 10 000 a day for five days Seconal, from 3 to 6 grains a day, was used as a sedative The laboratory reports were as follows Urine—acid, 1 018 specific gravity, no albumin no glucose, hemoglobin—84 per cent, white blood cells, 9 550—76 per cent neutrophiles, 24 per cent lymphocytes There was some difficulty in swallowing for a few days, but at no time
sary His convalesc
was discharged on A
little of the stiffness in his back and neck muscles, but this soon disappeared

Comment

In years past tetanus was classed as traumatic or idiopathic, today all cases of tetanus are considered to be traumatic in origin even though a source of entry cannot be found Among other portals for the tetanus bacillus, Williams and McClure[1] mention insect bites, vaccinations, extraction of teeth, trauma caused by picking the nose, burns, frostbite, subungual hematoma, hypodermic injections, sutures of catgut, in other words, any one of a number of insignificant traumatic lesions could be the portal of entry Our farmer, H B, had daily contact with the proper soil to grow tetanus, and he developed the disease at the peak of the season—July, but there was never any way of deciding the time or the place the bacilli entered his body

The question may be raised as to whether the administration of 70,000 units of antitoxin eleven days after the onset of stiffness of the neck muscles had any curative effect Perhaps not, if we accept the dictum of Shumacker, Firor, and Lamont[2] that antitoxin has no therapeutic effect once a lethal amount of toxin has been fixed by body tissues, and the period of incubation of fixation has passed

However, therapy in practice is not ordinarily influenced by side-chain theories and we did the usual thing of following the diagnosis of tetanus by the administration of antitoxin.

The main interest in the case as far as we were concerned was the one of differential diagnosis. Only after following the progress of this patient from day to day and reading the literature did it become clear that a case of tetanus could on occasion resemble closely an ordinary stiff neck.

ARMY'S NEW PLASTIC EYE

A new plastic eye is being made by the Army which is lighter and more durable than glass, can be tinted to duplicate the appearance of the natural eye, and fitted to provide as much mobility as possible, thereby avoiding the appearance of staring.

First step in making the eye is to paint the "iris"—a thin celluloid disk, only one-ten-thousandth of an inch thick. The "iris" is then embedded in a tiny plastic lens of acralain—a plastic that has been used in dentistry for the last ten years. The impression of the patient's eye socket is made with a new type compound, an alignate plastic, that is chemo-setting. This, mixed with water to make a paste, is injected with a syringe under the eye-lid at body temperature without causing pain or discomfort. It sets to a rubber-like consistency in five minutes and is removed painlessly, giving a permanent record of every tissue contour within the socket. A plaster cast is then made from this replica and used to mold a wax model of the eye-ball. The iris button is fitted into the wax and the whole unit is then fitted to the patient. The body temperature melts the wax slightly to produce an even better fit.

A second cast is then made from this wax replica and the wax is melted away and the cavity filled with acrylic resin, tinted the shade of the patient's natural eye-ball. This is baked for an hour under a half ton of pressure. When it comes from the cast it has on its front surface the tiny disk of the iris.

It is then polished and the "veins" are applied—tiny rayon fibers, an innovation by Capt. Don Cash, of Beaumont General Hospital, El Paso, Texas. As a final step, the whole eye is dipped in a clear plastic solution which produces a gleaming coating similar to the layer of liquid covering the natural eye. This plastic eye is so durable it can be dropped on the floor and stepped on without injury.

Credit for developing the eye goes to three dental officers: Capt. Stanley F. Erpf, Maj. Milton S. Wirtz, and Maj. Victor H. Dietz, who were working independently before they were brought together at Valley Forge General Hospital to found the artificial eye laboratory. Technicians are now being trained within thirty days to make these eyes.—*Release from the Office of the Surgeon General, Dec. 30, 1944*

THE 4-F'S AMONG MILITARY GENIUSES

With all our present-day emphasis on physical fitness, it is well to remember that, through the workings of the ineffable law of compensation, genius has been found most generally among the 4-F's. While this is no reason for cultivating malaise, or for abandoning our programs of rehabilitation, it should give us pause to consider that there may be estimable values other than big muscles and rosy cheeks.

Even in the field of military service, where 4-F's are about as plentiful as meat dealers at a vegetarians' convention, the physically handicapped has, historically, carved out quite a record for himself.

Witness the following list of military and naval geniuses cited recently by Dr. Logan Clendening in his volume, *The State of the Nation's Health.* As Dr. Clendening suggests, "a great many of the world's greatest officers would have been rejected by the draft boards":

Name	*Reason for Rejection*
George Washington	False Teeth
Bismark	Overweight
Napoleon	Ulcer of the Stomach
U. S. Grant	Alcoholism
Julius Caesar	Epilepsy
Horatio Nelson	One Eye, One Arm
Kaiser Wilhelm	Withered Arm
Genghis Khan	Paranoia
Duke of Wellington	Underweight

FOREIGN BODY IN THE ABDOMEN INTRODUCED THROUGH THE VAGINAL ROUTE—CASE REPORT

A LESTER WEISBERG, M D , BRONX, New York

(Assistant visiting surgeon, Morrisania City Hospital, assistant adjunct visiting surgeon, Bronx Hospital)

A WOMAN was admitted to the surgical service of the Morrisania City Hospital on November 28, 1943 * To the admitting physician she told a story of having fallen in the hospital four days ago while visiting her child Since then she had had pain in the abdomen, particularly on the right lower side On examination, the admitting physician found tenderness, some rigidity, and rebound tenderness

[illegible] operature of
[illegible] itive to a
[illegible] tentative
[illegible] of chronic
[illegible] ne history
[illegible] omen and

pelvis Much to his amazement, the x rays revealed the presence of a length of rubber catheter completely within the abdomen, up to the level of the upper border of the third lumbar vertebra

History —Confronted with the evidence of the x-rays, she finally gave the following history She was 27 [illegible] of age Her periods very twenty-eight d e she became 15 years of age Having had no period since the birth of her youngest child, five months ago, she had an Ascheim-Zondek test done, which was positive, two weeks previous to admission One week after, she had a rubber catheter inserted into the uterus by a midwife, and was told the catheter would fall out in several days However, the catheter did not appear, and for the past four or five days she had been having pains in the right lower quadrant of the abdomen She stained only for two days, and passed no clots nor any products of conception The story of having fallen in the hospital was a pure figment of her imagination, for she was ashamed to admit the episode with the midwife

Physical

a young,
woman, not

The heart and lungs were normal, pulse rate was 120, regular, and of good quality, and the blood pressure was 110/60 The temperature was 103 8 F , the urine was normal, and the blood count was 16,000 white cells with 88 per cent polymorphonuclears, and 3,170,000 red cells Abdominal examination revealed marked tenderness, moderate rigidity and rebound tenderness over the right lower quadrant, and some tenderness over the left lower quadrant Bimanual examination revealed a uterus only slightly enlarged, and considerable tenderness in the right fornix Visualization of the cervix did not reveal any foreign body protruding through the cervical canal, nor was there any evidence of perforation of any of the fornices The diagnosis was made of perforation of the uterus by a catheter, with localized abscess, and of the presence of the catheter in the abdominal cavity She was operated upon the same day after having received 500 cc of blood

Upon opening the peritoneal cavity through a right rectus incision, a small amount of turbid fluid appeared, but much to my chagrin, no catheter was visible or palpable The fimbriated end of the tube, markedly thickened, was overlying the right broad ligament, and covered by a plastic exudate The uterine end of the tube was normal The uterus was soft and only slightly enlarged No perforation was visible The thickened end of the tube was gently freed from the underlying broad ligament, and there, barely perceptible, was a small perforation of that ligament With slight pressure of each hand on either side of the perforation, there appeared through it the lower end of the catheter This was grasped with a forceps and removed Apparently the catheter had coiled itself up between the layers of the broad ligament Ten Gm of sulfanilamide was placed in the abdomen, and two cigarette drains were inserted, one over the site of the thickened tube and perforated ligament, and the other in the pelvis The tube was not resected nor was any exploration done The abdomen was closed in layers

Postoperative Course —On the first postoperative day, the temperature came down to 101 F The red count that day was 4,010,000 red cells and 56 per cent hemoglobin She was given another transfusion of 500 cc of blood On the second postoperative day, her temperature rose to 103 8 F , which may have been caused by a transfusion reaction However, sulfadiazine therapy was instituted at this stage, 2 Gm immediately and 1 Gm every four hours thereafter Her temperature came down to normal within thirty six hours, where it remained until December 8 and 9, when it ranged between 102 and 103 F The abdomen then was soft, there was no distention, no tenderness or spasticity Rectal examination revealed no evidence of a pelvic abscess However, after expressing about one dram of purulent material from the site of the emergence of the drains, the temperature promptly returned to normal, where it remained until her discharge from the hospital on December 12, the fourteenth postoperative day The abdominal incision healed by primary union Since her discharge from the hospital, she has had regular, normal periods

Had x-rays not been taken in this case, revealing the presence of a rubber catheter, it is very likely [illegible] ny, the diagnos[illegible] ave been made [illegible] have remained [illegible] gament, undiscovered

* From the surgical service of Dr George E Milam

PUBLIC VS TB

The battle against tuberculosis is not a doctor's affair, it belongs to the entire public —*Sir William Osler, in Tuberculosis Clip Sheet, Oct , 1944*

TUBERCULOSIS IN THE AGED

There has been a gradual and noticeable increase in morbidity of tuberculosis in the aged —*Arthur Rest, M D , Am Rev Tuberc , Mar , 1942*

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. *The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D., and Charles D. Post, M.D.*

Diseases of the Skin

POSTGRADUATE instruction was held before the Broome County Medical Society on February 13, at 8:30 P.M., in the auditorium, Binghamton City Hospital, Binghamton.

Dr. Leon H. Griggs, associate professor of clinical medicine (dermatology and syphilology) at the Syracuse University College of Medicine, delivered a lecture entitled "Common Diseases of the Skin."

The lecture was illustrated with color photography.

Two Lectures for Tompkins County

POSTGRADUATE education has been arranged for the Tompkins County Medical Society, to be given Tuesday evenings at 8:30 P.M. at the Nurses' Home, Tompkins County Memorial Hospital, Ithaca.

One lecture took place on February 20. It was "Penicillin Therapy," by Dr. Howard B. Slavin, assistant professor of medicine and bacteriology, University of Rochester School of Medicine and Dentistry. On March 20 Dr. Barton F. Hauenstein, assistant professor of medicine at the University of Buffalo School of Medicine, will speak on "The Present and Postwar Importance of Malaria, Filariasis, and the Dysenteries."

This instruction is provided by the Medical Society of the State of New York with the cooperation of the New York State Department of Health.

Injuries of the Extremities

THE Cortland County Medical Society will meet on March 16 at 8:30 P.M. at the Cortland County Hospital, Cortland, for postgraduate instruction.

Dr. P. K. Menzies, professor of clinical surgery at the Syracuse University College of Medicine, will discuss "The Treatment of Injuries to the Hands and Feet."

This instruction is provided by the Medical Society of the State of New York with the cooperation of the New York State Department of Health.

General Medical Lectures in Saranac Lake

THE Saranac Lake Medical Society met on January 31 at 8:00 P.M. in the John Black Room, Saranac Laboratory, Saranac Lake, for a lecture entitled "Management of the Failing Heart," given by Dr. Harry Gold.

Dr. Gold is assistant professor of pharmacology, department of pharmacology, Cornell University Medical College, New York City.

On March 28, at 8:00 P.M., the society will meet again at the same place. A lecture, "Cancer of the Oral Cavity," will be given by Dr. Hayes Martin, assistant professor of clinical surgery at Cornell University Medical College, New York City.

The latter lecture will be presented by the Medical Society of the State of New York with the cooperation of the New York State Department of Health.

Hematology

POSTGRADUATE instruction was given before the St. Lawrence County Medical Society on February 8 at 12:15 P.M. at the Arlington Inn, Potsdam.

Dr. Ellery G. Allen, associate professor of clinical medicine and assistant professor of clinical pathology at the Syracuse University College of Medicine, was the speaker.

He gave a lecture entitled "General Résumé of Hematologic Disorders Including the Anemias."

Jefferson County Series

TWO lectures have been arranged for the Jefferson County Medical Society, for Thursday evenings at 6:00 P.M. at the Black River Valley Club, Watertown. The first, which was given February 8, was "General Résumé of Hematological Disorders Including the Anemias," by Dr. Ellery G. Allen, of the Syracuse University College of Medicine.

The second will be given on March 8. It is "The Treatment of Pneumonia," by Dr. Russell L. Cecil, professor of clinical medicine at Cornell University Medical College, New York City.

The instruction on pneumonia is provided by the Medical Society of the State of New York with the cooperation of the New York State Department of Health.

Medical Legislation

Bulletin No. 2 issued by the Legislative Bureau of the Medical Society of the State of New York, January 20, 1945.

THE L[illegible] many bills a[illegible] im- possible [illegible] time to make [illegible] in- formatio[illegible] beg your indulgence and omit any special comments on these bills.

The chiropractic bill (*Senate Int. 94—Scelye; Assembly Int. 98—*[illegible] mittee in both [illegible] is possibility of [illegible] some indications that the chiropractors feel confident that they have sufficient votes to pass this bill at the present time. It is extremely important that all who can, contact, write, or communicate with the legislators from their districts urging that this bill be kept in committee until the latter part of February or early March if possible. It is important, also, that as many responsible persons of the community be urged to write a letter to the legislators against this bill as can be persuaded to do so.

Our purpose in defeating this bill is to protect the public from incompetency in the practice of medicine. If the chiropractors met the educational requirements laid down for the practice of medicine and passed a proper examination, there would be no objection against the chiropractors, or practitioners from any other school of medicine, obtaining licensure for the practice of medicine.

Many of the legislators are thoroughly exasperated with this fight which has come up year after year. They consider it a controversial issue and have been impressed by arguments that some control should be placed on the chiropractors, as they are practicing every day in the year in the State and the courts have not been successful in eliminating this practice. One of the other arguments produced, also, is that as there are about forty states which now license chiropractors, the chiropractors that are unsuccessful in obtaining admission to [illegible] can practice [illegible] at New York [illegible] -actic quacks who are not able to obtain licensure in other states. No evidence has been produced that there has been a recent influx of chiropractors to New York State. The main question, however, remains that the practice of chiropractice is the practice of medicine. They should be required to have a thorough basic knowledge of medicine in order to make proper diagnosis as a protection to the patients they propose to treat, and without thorough scientific training in this [illegible] our progress along these lines. May we urge you again to use your influence among members of your community to bring immediate pressure on their legislators?

We are sending you at this time the list of Senate Committees with which we usually work.

New Bills Introduced

Senate Int. 132—Parisi; Assembly Int. 149—Crews, requires payment of workmen's compensation for partial disability due to silicosis or other dust diseases, or diseases resulting from metallic gases or industrial chemical processes or allergic diseases; increases the aggregate to total compensation from $5,000 to $10,000 for temporary total and from $6,500 to $10,000 for permanent total disability or death; minimum weekly compensation is increased from $8.00 to $20 and maximum from $25 to $35. Referred to the Labor Committees.

Senate Int. 212—Novod, requires the administration of blood transfusions for persons in immediate need in public hospital and provides for state reimbursements of costs if payment is not made by the persons responsible; $50,000 is appropriated to the Health Department. Referred to the Finance Committee.

Senate Int. 216—Pack, increasing the number of commissioners of State Insurance Fund. Referred to the Labor Committee.

Comment; Same as *Assembly Int. 110—Quinn,* reported in Bulletin No. 1.

Senate Int. 218—Pack, defining occupational diseases for workmen's compensation benefits and repealing the [illegible] dust diseases.

Comment

reported in Bulletin No. 1.

Senate Int. 273—Young, provides that no person shall serve as State Regent after the April 1 next [illegible] t the shall Committee.

Senate Int. 320—Graves; Assembly Int. 387—Parsons, provides for uniform sanitary requirements and inspection by the State Health Department of dairy farms, receiving stations, and other milk plants; authorizes the [illegible] to issue permits for the [illegible] milk products; $396,0[illegible] ferred to the Finance Committee in the Senate and the Ways and Means Committee in the Assembly.

Senate Int. 367—Hammer; Assembly Int. 283—Stuart, allows the local health officer additional pay for investigations in cases of death without medical attendance and includes Indians on reservations to be counted in determining his salary; payment for service and expenses in suppression of rabies shall, instead of may be, paid by the fiscal officer of the health district or pursuant to local finance law. Referred to the Health Committees.

Senate Int. 368—Hammer; Assembly Int. 254—Stuart, authorizes the Health Commissioner to embargo any part of a milk supply so contaminated as to be dangerous to health or if curtailment of supply is threatened as a result of accident, sabotage of enemy action pending investigation, and to authorize transfer from one plant or municipality to another for pasteurization, bottling, or sale; the emergency provision for embargo expiring July 1, 1945, is repealed. Referred to the Health Committees.

Senate Int. 369—Hammer; Assembly Int. 284—Stuart, includes the county health district in the definition of the health district for regulation of venereal and certain other contagious diseases. Referred to the Health Committees.

Senate Int. 370—Hammer; Assembly Int. 255—Stuart, strikes out the reference to inspection by the director of laboratories and research division in the Health Department of Laboratories outside of New York City. Referred to the Health Committees.

Senate Int. 371—Hammer; Assembly Int. 286—Stuart, strikes out the provision that the superintendent of each state hospital and institution and the director of the State Institute for Malignant Diseases shall be in a competitive civil service class. Referred to the Health Committees.

Senate Int. 372—Hammer; Assembly Int. 445—Chase, gives the New York City health commissioner jurisdiction of permits for the possession or cultivation of live pathogenic micro-organisms or viruses other than vaccine virus, and changes the provisions relative to registration and sale. Referred to the Health Committees.

Senate Int. 373—Hammer; Assembly Int. 444 Chase, provides that the possession of a forged narcotic prescription by a person other than an apothecary pursuing his profession shall be presumptive evidence of intent to use same for illegally obtaining a narcotic drug and makes other changes relative to narcotic drugs. Referred to the Health Committees.

Senate Int. 381—Warner; Assembly Int. 311—Morgan, creates a commission of three senators, three assemblymen, and three persons appointed by the Governor, to be known as the New York Commission on Physical Fitness, to promote physical fitness through physical training, athletic sports, recreation, and camping; $75,000 is appropriated. Referred to the Defense Committee in the Senate and the Ways and Means Committee in the Assembly.

A resolution was made by Mr. Hammer creating a committee to study public health laws, particularly provisions relating to foods and drugs; also other laws which relate to the sale and preparation of food, foodstuffs, and drugs, providing for a report on February 1, 1946, and appropriating $15,000. To Finance Committee.

Assembly Int. 141—Jack, establishes in the Health Department a health insurance fund with an administration board of thirteen members appointed by the Governor; the fund is to be maintained by contributions of employees, employers, and the State, and provides for payment of cash benefits and for maternity and other medical care; allows persons of low income to insure in the system, and appropriates $1,000,000. Referred to the Ways and Means Committee.

Assembly Int. 154—Gittleson, provides that, after the filing of hospital liens in cases of accidents, the injured person or his legal representative in case of death, or the person responsible for the injuries or the hospital may require the court to determine and fix reasonableness of the lien. Referred to the Judiciary Committee.

Assembly Int. 175—Farbstein, requires city education boards and school districts maintaining public schools to provide adequate health service for pupils 15 years of age and over, and facilities to afford physical examination including x-raying of chest; the State War Council may help districts financially unable to provide services. Referred to the Education Committee.

Senate Committee on Codes

*Fred A. Young, *Chairman*	F. R. Coudert
W. J. Mahoney	J. D. Bennett
P. W. Williamson	J. V. Downey
E. S. Warner	R. H. Rudd
R. A. DiCostanzo	Isidore Dollinger
G. H. Pierce	L. L. Friedman

Senate Committee on Finance

*A. H. Wicks, *Chairman*	G. T. Seelye

* Indicates new chairman for 1945.

Bulletin No. 3 issued by the Legislative Bureau of the Medical Society of the State of New York, January 29, 1945.

New Bills Introduced

Senate Int. 467—Burney; Assembly Int. 638—Volker, provides reasonable cost to municipality of medical examination, including chemical analysis, of a person arrested for operating a motor vehicle

or motorcycle while intoxicated, and the cost of court attendance of the person making analysis shall be a charge against the State Referred to the Motor Transportation Committee in the Senate and the Motor Vehicles Committee in the Assembly

Senate Int 476—Joseph, health insurance bill Referred to the Finance Committee

Comment Same as *Assembly Int 141—Jack*, reported in Bulletin No 2

Senate Int 506—Burney, Assembly Int 560—Pillion, continues to July 1, 1946 the provision permitting a person inducted into military service and licensed to practice medicine, dentistry, and other professions and occupations to apply for renewal of license without examination within three months after the termination of military service Referred to the Defense Committee in the Senate and the Education Committee in the Assembly

Comment Continues the provision passed in 1944 for a year

Senate Int 510—Condon Assembly Int 646—Crews, creates a workmen's compensation board to take the place of the industrial board, at expiration of the term of the present members terms are to be staggered so that a minimum number will be chosen each year, places the quasi judicial functions concerning workmen's compensation and the administrative work relating thereto under control of the board, referees are to be appointed by the board and are to act under the supervision of the chairman Referred to the Labor Committees

Comment A long bill which is along the lines recommended to improve the Workmen's Compensation Law reducing conflict of overlapping authority

Senate Int 515—Hammer, changes provisions for examination or quarantine of persons suspected of venereal disease and for the treatment or quarantine of persons infected Referred to the Health Committee

Comment Same as *Assembly Int 434—Stuart*, reported in Bulletin No 2 Extends the control of venereal disease

Senate Int 539—W J Mahoney, Assembly Int 556—Mailler, continues to July 1, 1946, the provision permitting practice of medicine in a hospital by physicians and interns with certain educational qualifications and provisions relating to medical students performing clinical clerkship Referred to the Education Committees

Comment Extends for a year the amendment which has been extended each year during the period of the war

Senate Int 573—Bennett, Assembly Int 695—Barrett, provides that home relief shall, instead of may be, granted in cash except that, where granting of cash may be deemed impracticable, it may be granted by order, medical, dental, and nursing care, including drugs and medical materials and supplies, may be granted by order Referred to the Relief and Welfare Committee in the Senate and the [illegible] embly

Senat [illegible] les for settlem[illegible] work-men's [illegible] referee deems [illegible] period of the disability does not exceed six weeks and the claim is not for permanent partial disability, the medical question may be submitted to a physician designated by the department, and the claimant, within one year after award or ruling on the submitted claim, may object and have the claim treated as a controverted claim, referees after September 1, 1945, shall be attorneys-at-law and no person except an attorney shall appear for the claimant on and after that date, with certain exceptions, makes other changes relative to settlements and compromises Referred to the Labor Committee

Comment The purpose of this bill is to speed up settlement of compensation claims

Senate Int 624—Desmond, regulates the manufacture and sale of bread and flour and requires the enrichment thereof to protect and promote public health and welfare, defines "enriched" as the addition of vitamins and other ingredients to make them conform to standards fixed by order of the Federal Security Agency on July 1, 1943 requires that flour or wrapped white bread or rolls shall be labeled to conform to the Federal food, drug, and cosmetic act, $25,000 is appropriated to the Agriculture and Markets Department Referred to the Finance Committee

Comment Provides State Law enforcing standards fixed by the Federal Security Agency and recommended by the National Research Council

[illegible] workmen's [illegible] chefs in [illegible] ardous for such purposes work in restaurants, bars, grills, lunchrooms, and luncheonettes Referred to the Labor Committee

Assembly Int 588—Mailler, relative to the length of term of the State Regent Referred to the Education Committee

Com[illegible] ent Same as *Sen[illegible] Int [illegible]—Young*, re-[illegible] nlawful for a person to manufacture or sell flour or bread and rolls unless they have certain specified vitamin and mineral contents until the Agricultural Commissioner shall establish other standards Referred to the Agriculture Committee

Comment Similar to but not the same as *Senate Int 624*,

Assembly Int 748—Preller, changes the classification of hospital nurses in civil service positions Referred to the Civil Service Committee

Comment Same as *Senate Int 54—Halpern*, reported in Bulletin No 1

Assembly Int 750—Knauf, makes it a misdemeanor to include in any newspaper, radio, display sign, or other advertisement any statement which misrepresents material, frames or mounting, or price of lenses or of complete eyeglasses, or to advertise frames unless the price of the frame is advertised with the words "without lenses" or to misrepresent service or credit terms Referred to the Codes Committee

A resolution was made by Mr Fogarty, creating a committee to study the Workmen's Compensation Law, the administration of same, existing defects therein, etc, providing for report February 1, 1946 and appropriating $50,000 Referred to the Ways and Means Committee

A resolution was made by Mr Graci, creating a committee to study and make an analysis of laws pertaining to health, including laws relating to sale and preparation of food and drugs (Identical resolution by Senator Hammer, Bulletin No 2) Referred to the Ways and Means Committee

A resolution was made by Mr Knauf, creating a committee to [illegible] supplies to the [illegible] ards may be p[illegible] ing of optical [illegible] all convenient [illegible] referred to the Ways and Means

Assemblyman DeSalvio has introduced bill *Int. 574* which permits the industrial board in workmen's compensation cases to make award for serious disfigurement instead of disfigurement in certain areas.

THE PLACE OF PREVENTIVE MEDICINE IN THE MEDICAL CURRICULUM

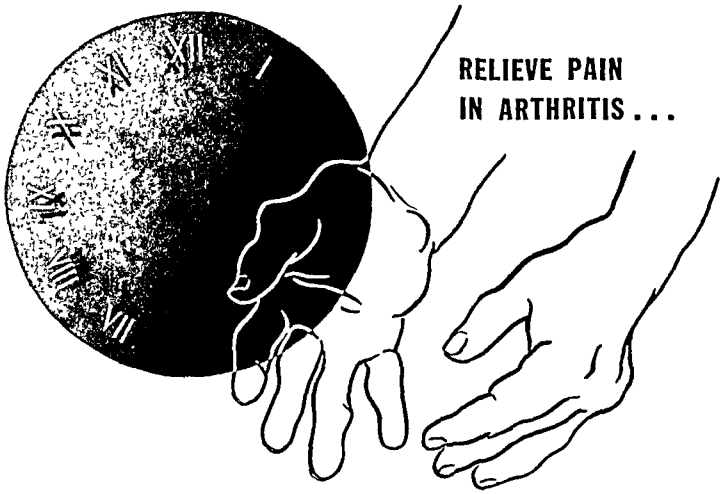
The Conference of Professors of Preventive Medicine, held at the time of our New York meeting, staged an interesting discussion on the role of courses in preventive medicine in the education of the physician.

It was generally agreed that public health is a field for postgraduate training but that preventive medicine is an essential part of the training of the medical student. An important point was raised, however, by speakers who contended that this subject might well be taught as a part of other courses and not as a separate item in the curriculum.

Clearly this is a counsel of perfection. The day may come when personal hygiene is taught as a part of physiology and when the clinical branches of medicine are developed not only from a preventive aspect but also with a view to that constructive medicine which visualizes the ideal of health in a positive sense as the goal of the physician. Were such ideals generally realized (as they are today in some pediatric faculties) no separate department of "preventive medicine" might be needed. That day, however, is far in the future.

Even in such a Utopian situation, there is one basic element which it would be essential to add to the curriculum. Nowhere (except in "preventive medicine" or "public health" does the medical student receive instruction in the basic and fundamental influences on health of the physical and social environment. When the work of the clinical years has become thoroughly permeated with a preventive and constructive viewpoint, there will still be need for a special course, (perhaps preclinical) in environmental therapeusis, covering the influences of sanitation and of the community machinery and social factors influencing physical and emotional well-being. This is a subject quite as important as materia medica.

Finally, in considering the basic problem of arousing in the medical undergraduate a really vital interest in prevention, we should not forget the obstacles placed in our way by the present economic basis of medical practice. So long as the doctor is paid on a fee-for-service basis, his income and his opportunity for service must depend on the treatment of disease, since he will be called in only when something hurts. The medical student subconsciously realizes this fact and inevitably feels that prevention, if not hostile to his interests, is at least irrelevant to them. Only when the doctor is habitually employed on a prepayment basis for health service will preventive and constructive medicine really become vitally significant.—*Am. J. Pub. Health, Dec., 1944*



A TRIBUTE TO THE AMERICAN MEDICAL ARTIST

A showing of medical art comprising the work of leading artists associated with medical schools and clinics from coast to coast opened January 8 at the Enoch Pratt Free Library in Baltimore and continued until January 29. The Department of Art as Applied to Medicine of the Johns Hopkins Medical School loaned a fine collection of the work of the late Max Brodel which was a focal point of interest in the display. For many of the out-of-town artists this exhibition is actually a homecoming as they studied in Baltimore with Mr. Brodel.

Represented are his daughter, Elizabeth Brodel, now with New York Hospital; William P. Didusch and Dr. Harry Wilmer, of the Johns Hopkins Hospital; James F. Didusch, of the Carnegie Institute of Washington and the Johns Hopkins Medical School; Ranice W. Birch, of the Department of Art as Applied to Medicine, Johns Hopkins Medical School: Jean Hirsch, University of Minnesota; Gladys McHugh, University of Chicago; Theodora Bergsland, Western Reserve, Cleveland; Helen Lewis Loud, Lahey Clinic; Mildred Codding, Peter Bent Brigham Hospital and Harvard Medical School; Evelyn Erickson, Wayne University Medical School, and Russell Drake, Mayo Clinic. Other exhibitors included Tom Jones, head of the Department of Art, University of Illinois; W. C. Shepard, Mary Dixon and Lucille Cassell of Northwestern University; Kay Bell, Kansas School of Medicine; Ralph Sweet, University of California; Helen Williams, Western Reserve University; Armen Hemberger, Yale; Vera Morel, Tulane University; Ruth Bialek, University of Maryland.

The exhibit, which is arranged by Modern Medicine, as a tribute to the American medical artist, was shown during February in Rochester at the Public Library.

WILLIAM F. MARTIN, ESQ.
Counsel, Medical Society of the State of New York

Hospital's Liability for Acts of Nurses

MANY years ago the courts of this State adopted a rule of law affording to charitable hospitals considerable immunity from liability for the professional acts of the physicians or nurses on their staffs. Although there are exceptions to that rule, it is still valid as a general principle of law, as is evidenced by the result in a case which was recently handled by your Counsel.*

The plaintiff in the case, an elderly woman, fell at home, sustaining a fractured femur. She entered a hospital where her personal physician, Dr. S., operated upon her to reduce the fracture. She was returned to her room in the surgical ward, and it was soon found that she was noisy and disturbing other patients, so the doctor ordered her put in bed in the solarium. Dr. S. directed the nurses to keep a close watch of the patient because of her disturbed condition.

From 9 P.M., when the plaintiff was put in the solarium, until 3:30 A.M., she remained quiet, and was seen by various nurses, who observed her apparently to be sleeping. At 3:30 A.M., however, a nurse observed that the patient had removed the operative dressing, and had become noisy. A house physician was called and a drug was administered. From then until a few minutes before 7 A.M. she was constantly attended by at least one nurse. During that period of time a second sedative was given, and when at the end of that time the patient was left alone, the nurses had concluded that the patient was quiet enough to be left unattended for a brief interval.

A few minutes later, while no nurse was actually present, the patient managed to fall from the bed to the floor and sustain injuries which concededly aggravated her condition.

She brought suit against the hospital, charging it with responsibility for the alleged negligence of the nurses, in that the patient had fallen when unattended.

The case came on for trial as a jury case. The proof was substantially as set forth above. It appeared that the plaintiff was a paying patient at the hospital, and it also appeared as unquestioned that the hospital was a charitable, not-for-profit institution. There was no proof that the patient's physician had ordered constant watching, although he had pointed out the disturbed condition of the patient to the nurses. The proof showed that there was a suitable number of nurses on duty, and there was no proof of incompetence on the part of any of the nurses.

At the conclusion of the testimony, the trial judge dismissed the complaint on the grounds that there was no *prima facie* case for submission to the jury. The plaintiff appealed to the Appellate Division of the Supreme Court and that Court affirmed the judgment in favor of the hospital. In so deciding the Court was not unanimous and two opinions were written in support of the affirmance and another opinion was written in dissent.

In the course of the opinion for affirmance written by Mr. Justice Heffernan, the following summary of the applicable law was made:

"It is conceded in this case that defendant is a charitable corporation established for the care of sick and indigent persons. The fact that it received compensation from some of its patients, as in the case of plaintiff, does not affect in any respect its eleemosynary character or liability as a public charity. Defendant undertakes not to heal or attempt to heal through the agency of physicians and nurses, but merely to supply them in order that they may minister to the needy on their own responsibility. In this State an exception to the doctrine of *respondeat superior* has been adhered to consistently. Doctors and nurses, so our courts have held, are not the agents and servants of a charitable corporation, but rather independent contractors for whom the hospital has provided a place to aid the suffering.

"It may well be that charitable corporations should not be immune from liability for the torts of their agents. The Court of Appeals has taken a long step in that direction in *Sheehan vs. North Country Community Hospital* (273 N.Y., 163). Notwithstanding the court's pronouncement in that case it is still the law of this State that a charitable corporation will be held liable for the torts of its mere servants or agents but not for those whom the court considers to be independent contractors such as physicians, surgeons, nurses, professors, instructors, and the like, if it has exercised reasonable care in their selection and retention. The doctrine of *respondeat superior* cannot be invoked as to them, because there is no relationship of master and servant upon which to predicate it. To enable such an institution to protect itself behind the shield of immunity it is only necessary to show due care in the selection and retention of those who serve it in the capacities indicated." (citing cases)

"It is not without significance that plaintiff's action is predicated solely on the negligence of defendant's nurses. No claim is asserted that defendant breached any contract, express or implied, with plaintiff. There is no contention that defendant was negligent in the selection of its nurses; in fact it is not even asserted that defendant's nurses were incompetent. Negligence in this case, if negligence there be, which is extremely doubtful, is bottomed solely on the negligence of defendant's nurses. Defendant, on the record before us, is not answerable for the tortious acts of its nurses."

In the course of his opinion, also for affirmance, Mr. Justice Crapser stated, in part:

"The defendant hospital fulfilled its obligations; it placed the patient in a suitable and safe place

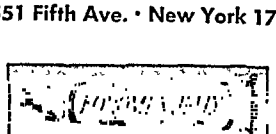
recent extensive investigation confirms contraceptive effectiveness of the active ingredient in Koromex Jelly

A most illuminating report based on extensive clinical and experimental data has recently been published by Eastman and Scott (Human Fertility, 9:33, (June) 1944.) These authors studied the safety and efficacy of phenylmercuric acetate which is the active constituent of Koromex Jelly.

1 Clinical evidence showed that in actual use, phenylmercuric acetate jelly had a remarkable record for contraceptive efficiency.

2 The earlier work of Baker, Ranson and Tynen (Lancet, 2:882, (October 15), 1938), showing a very high spermicidal potency, was confirmed.

3 Toxicity was found low.



4 No evidence of irritability on the part of either the husband or wife.

In addition to the above qualities, Koromex Jelly, which also contains oxyquinoline benzoate and boric acid in a well buffered glycerine gum base, has the properties of adhering firmly to the vaginal lining and mixing readily with the vaginal secretions. It has optimum spreading qualities. Its pH of 4.6 is constantly maintained even in the presence of the buffering action of the protein seminal fluid.

Koromex Jelly does not stain. It is not excessively lubricating, and is well tolerated. Because of these qualities you can assuredly — prescribe Koromex *with confidence.*

[Continued from page 542]

as ordered by her doctor. It furnished ample nursing facilities to the patient and her physician. There was no special nurse ordered on the case by her doctor. His orders were carefully carried out. The hospital's obligations were fulfilled according to all the evidence in the record.

"The relation between a hospital and its physicians is not that of master and servant but merely to procure them to act upon their own responsibility. When nurses or physicians are treating a patient they are not acting as servants of the hospital. It is true that the superintendent, assistant superintendent, orderlies, and members of the administrative staff are servants of the hospital but nurses are employed to carry out the orders of the physician, to whose orders they are subject. The hospital undertakes to procure for the patient the services of a competent nurse; it does not through the agency of the nurses render those services itself."

The plaintiff took the case to the Court of Appeals, and although that Court wrote no opinion in connection with its decision, the judgment in favor of the hospital was affirmed.

"DOCTOR JONES" SAYS—

"Jack Spratt could eat no fat and his wife could eat no lean, and so, betwixt them both" they probably violated most of the rules of good nutrition. It's conceivable, of course, that Mr. Spratt had something wrong with his digestion so he couldn't digest fats. And Mrs. Spratt—she might've had some disease or other that gave her an abnormal craving for fats. But the probabilities are their being so finicky was just the result of picking up foolish ideas when they were kids—maybe from the old folks.

However, I'm not so much concerned about the family history of the Spratts as I am about the nutrition of the children of the present generation. The science of nutrition—it's something we're just beginning to get to the bottom of. And, the better we understand it, the more we realize how important good nutrition is.

It don't mean just satisfying our appetites and keeping our figures stylish. It's a matter of getting the proper proportion of the right food elements. Lack of necessary food elements—it's been responsible for failures in life—millions of 'em—and even for wars being lost. And the thing of it is: most of our dietary habits are established in childhood.

A little girl I see frequently—she's somewhere around ten or eleven—she's got a face like a Madonna and a figure like a pillow with a string around the middle.

I practically never see her but what she's eating something; candy or an ice cream cone or what not. It's just simply overeating that's making her too fat. There are, of course, cases of excessive overweight that're due to a disorder of one of the endocrine glands but they're comparatively rare.

Anyway, this young lady—in a few years now she'll begin to give more thought to her figure. Then I s'pose she'll go on a diet—and probably overdo it.

Another girl, a little older, she's all for keeping her weight down. So she eats half a breakfast and goes without lunch. And she don't weigh any too much as it is. This "boyish figure" idea—why a girl should want to—well, anyway, one extreme's as bad as the other.

Somebody asked me, the other day, if I practiced what I preached. Well, teaching an old dog new tricks, you know—at any rate I'd like to see the young ones get started right.—*Paul B. Brooks, M.D., in Health News, Jan. 1, 1945*

TELEVISION IN HEALTH EDUCATION

The First Annual Conference of the Television Broadcasters Association was held at the Hotel Commodore, New York City, December 11 and 12. Thomas C. Stowell, assistant director of the Division of Public Health Education, attended the meeting as the representative of the New York State Department of Health.

Progress and postwar plans in television were outlined by recognized authorities, including Allen B. DuMont, president of the Association; Dr. W. R. G. Baker, vice-president of the General Electric Company, whose initials are borne by the General Electric Television Station, WRGB, Schenectady; John F. Royal, in charge of television, National Broadcasting Company; and Lewis Allen Weiss, executive vice-president of the Don Lee Broadcasting System on the west coast. Entertainment features consisted mainly of programs broadcast by television to the conference.

Information produced by Mr. Stowell at a panel meeting for program directors will be made the basis for plans to be developed by the Division of Public Health Education for utilizing television in health education work. Some of the health motion pictures produced by the Division have already been broadcast by television from the National Broadcasting Company's station in New York City, and negotiations are under way with the General Electric station in Schenectady for similar broadcasts.—*Health News, Jan. 1, 1945*

Army Awards Typhus Commission Medals to Ten

TWO American diplomats, five Army officers, and three Navy officers have received the Typhus Commission Medal for "exceptionally meritorious service" in the control and treatment of typhus, the War Department announced in Washington on February 4.

The Typhus Commission was authorized by President Roosevelt on December 24, 1942, as a joint organization of the Army and Navy for controlling and preventing the spread of typhus.

Laurence A. Steinhardt, now American Ambassador to Turkey, one of the ten receiving the medals, was cited for opening a cooperative project with the medical corps of the Turkish Army and the commission to fight typhus.

Col. Harry Plotz, of Brooklyn, received the medal because he "organized and directed the first laboratory provided abroad for study of the disease by Egyptian physicians at Cairo." He arrived there in January, 1943. As a commission member he is now chief of the virus and rickettsial disease division of the Army Medical School, stationed at Walter Reed Hospital, in Washington.

A medal for developing the research and diagnostic laboratory at Cairo was given to Lt. Col. John Crayton Snyder, formerly of New York City. He was cited for participating in development and trial of new methods of serum therapy and chemotherapy, for applying his knowledge to an outbreak of the disease in Naples late in 1943, where he had charge of a case-finding service, and for "untiring" research.

Alexander C. Kirk, Ambassador to Egypt, received the medal "for his great personal interest" and support of the Cairo project, which aided the commission's broadened activities in the Middle East. Capt. Thomas J. Carter, of the Navy Medical Corps, of Arlington, Virginia, was honored for his help in organizing the first overseas movement of the commission in December, 1942, and for personal attention to the participation of the Navy in the commission's function.

The two other naval officers who received medals for their work are Lt. Comdr. William B. McAllister, Jr., of Cleveland, and Lt. Comdr. Andrew Yeomans, of Brookline, Massachusetts.

Commander McAllister studied the disease as pathologist of the Cairo office in North Africa, and in the Middle East, contributing to the knowledge of the disease.

Commander Yeomans was cited for operation of an experimental hospital ward at Cairo, where he was under "constant risk of infection." He also made a survey of typhus in Naples which is credited with keeping down the fever's incidence there.

Maj. Charles M. Wheeler, of Brea, California, and Capt. Byron L. Bennett, of Boston, both members of the Army Sanitary Corps, were cited for their help in treating the disease.

Major Theodore E. Woodward, of Westminster, Maryland, who went to North Africa with the invasion forces in November, 1942, when he cooperated with French scientists of the Pasteur Institute at Casablanca, Morocco, in controlling the disease, also got a medal. He later worked in Naples and now represents the commission in the European theater of operations.

Six New Appointments to Advisory Group

THE names of six doctors who have accepted invitations to serve on the special Medical Advisory Group to the Administrator of Veterans' Affairs were announced on January 12 by Brig. Gen. Frank T. Hines, Administrator of Veterans' Affairs. These acceptances bring to fourteen the number of distinguished doctors who are now serving on this group, which has been selected to include leaders in all the major specialities of medicine.

When it is completed the group is planned to have fifteen members. The fifteenth invitation has been issued, but the name of the proposed member cannot be disclosed as a reply has not yet been received.

General Hines said this group will guide him in establishing policies and in solving the many perplexing problems that face the administration in the examination and treatment of thousands of young veterans who are being hospitalized as a result of this war. One of the primary problems is securing and training the highly qualified professional and subprofessional personnel needed to care for the increased number of hospital patients and expanding outpatient group coming to the Veterans Administration. Their services are expected to be invaluable in outlining and assaying research work in war medicine and making recommendations as to the desirability of results for incorporation in clinical and therapeutic practices in veterans' hospitals.

The six whose acceptance of appointment to this group was announced on January 9 are: Dr. Irvin Abell, of Louisville, Kentucky, professor of surgery, University of Louisville School of Medicine, past-president, American Medical Association, past-president, Southern Surgical Association, past-president, Gastro-Enterological Association, past-president, Southern Medical Association; Dr. Alfred W. Adson, of Rochester, Minnesota, senior neurosurgeon, Mayo Clinic, professor, neurosurgery, Mayo Foundation, past-president, Society of Neurological Surgery, member of the International Neurological Association, subcommittee, neurologic surgery, National Research Council; Dr. W. Edward Chamberlain, of Philadelphia, director of radiology, Temple University Hospital, professor of radiology, Temple University, member of the National Research Council, and American Radium Society, former chairman, Board of Chancellors, American College of Radiology, Radiological Society of North America; Dr. John S. Coulter, of Chicago, professor of physical therapy and in charge of physical therapy departments, Northwestern University, American Congress of Physical Therapy, Council on Physical Therapy; Dr. Malcolm T. MacEachern, of Chicago, associate director and chairman, administrative board, American College of Surgeons, former general superintendent, Vancouver General Hospital, Vancouver, B.C., member, Committee on Hospitals and Memorial Commission on Physical Rehabilitation, National Defense Advisory Council, advisory board, American Dietetic Association, advisory council, Association of Medical Social Workers; Capt. Erik G. Hakansson, of Bethesda, Maryland, medical director, U.S. Navy, Naval Medical Research Institute, National Naval Medical Center, Bethesda.

The eight who had previously accepted have been reported in a recent issue of the JOURNAL.

Sir Harold Whittingham Receives Aeromedical Award

SEVEN leaders in aeronautics, including Air Marshal Sir Harold Whittingham, director of Royal Air Force medical services, received awards at a meeting of the Institute of the Aeronautical Sciences in New York City, in January.

In accepting the John Jeffries Award for outstanding contributions to aeromedicine, Sir Harold said that there had been the closest cooperation between British and American researchers into aeromedicine.

The presentation was made by Maj. Gen. David N. W. Grant, air surgeon of the Army Air Forces.

County News

Albany County

The January meeting of the Albany County Medical Society, postponed from January 17 because of heavy snowfall, was held at 9 P.M. on January 24 in the auditorium of Albany College of Pharmacy.

Dr. Frank H. Lahey, director of the Lahey Clinic and trustee of Northeastern University, Boston, spoke on "Lesions of the Terminal Ileum, Colon, and Rectum." Discussion was opened by Dr. J. Lewi Donhauser, Dr. Stanley E. Alderson, and Dr. Arthur M. Dickinson.*

• • •

Regents of the state paid tribute to Dr. Arthur B. Van Loon, dean of Albany physicians, who served eighteen years on the Medical Grievance Committee of the University of the State of New York, at a dinner in his honor at the Union Club in New York City.

Dr. Van Loon, with the committee since its establishment in 1926, served as secretary and president but resigned last year because of pressure of his private practice. He has been associated with Memorial Hospital, Albany, for more than fifty years.

An inscribed plaque was presented him by members of the committee. Regent George H. Bond, of Syracuse, made the presentation. Vice-chancellor William J. Wallin paid tribute to the Albany physician for service he has given the medical profession.*

• • •

Dr. Esther McDonald Lloyd-Jones, professor of education, Columbia University, spoke at the annual luncheon of the Albany Visiting Nurse Association at 12.15 P.M., January 24, in Trinity Methodist Church, Albany.

The meeting was in cooperation with the Public Health and Maternal Welfare Committees of the county society. Reports were read by committee chairmen, with Mrs. Frank C. Hughson, president, presiding.

Dr. Lloyd-Jones, author of several educational books, spoke on "Toward Full Effectiveness."*

Columbia County

Dr. J. D. Hexom, of Decorah, Iowa, has opened an office in Chatham.

Dr. Hexom has, for the past twenty-five years, conducted a successful medical practice in Decorah. He was graduated from the Iowa State University Medical School.*

Erie County

Capt. Joseph Y. Spinuzza, of Buffalo, has retired from the Army Medical Corps and resumed the private practice of medicine at his residence. In service twenty-eight months, he was injured on tank maneuvers near Fitzsimmons General Hospital, Denver, Colorado, where he was last assigned. A practicing physician for seventeen years. Dr. Spinuzza was a member of the surgical staffs of Lafayette and Columbus hospitals before he enlisted in the Medical Corps in 1942.

• • •

Medicine and law joined hands in Buffalo on January 12 for the first of a series of round-table conferences designed to achieve important improvements in the operation and administration of the Workmen's Compensation Law Court of the Buffalo district office, State Department of Labor.

Meeting in the Hotel Statler offices of the county society, the society's Workmen's Compensation Board, the Workmen's Compensation Committee of the Erie County Bar Association, and referees of Workmen's Compensation Court discussed at length the common problems of the two professions in the trial and disposition of compensation cases.

They agreed unanimously to cooperate closely to correct numerous unsatisfactory procedures, and institute new methods, where needed, to expedite decisions on claims, assure claimants the full benefits of the law, and conserve the time of doctors and lawyers.*

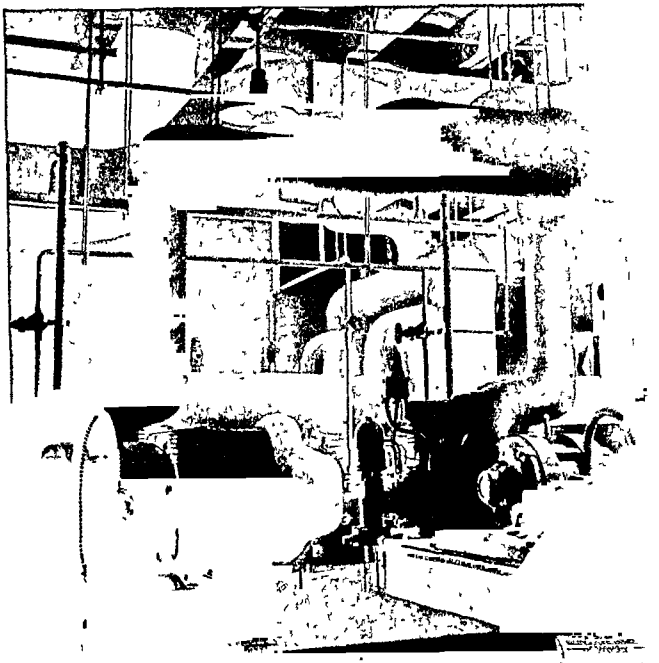
• • •

The *Erie County Medical Bulletin* appeared in a new expanded, reorganized form in January. It is expected that the new *Bulletin* will function more effectively and vigorously as a local instrumentality for the safeguarding and the promotion of the public health through its broader field of activity and influence.

Jefferson County

Dr. Walter G. Robinson, of Alexandria Bay, has announced that Dr. Robert Barker Burtch will be associated with him in the practice of medicine and surgery.

The two physicians will have their offices in the Kepler homestead next to the Noble Foundation Hospital. These offices, now occupied by Dr. Robinson, will be enlarged to accommodate the two doctors.



Dr. Robinson served in the Army Medical Corps from March, 1941, to January, 1942. Dr. Burtch is a flight surgeon in the Naval Medical Corps, with the Pacific fleet.*

• • •

The regular monthly meeting of the county society was held on February 8 at the Black River Valley Club. Dr. Ellery G. Allen, assistant professor of clinical medicine, Syracuse University College of Medicine, delivered a lecture entitled "General

Résumé of Hematological Disorders Including the Anemias."

Monroe County

Dr. J. Rodney Heller, director of the Division of Venereal Disease, United States Public Health Service, was the guest speaker at a luncheon meeting held in observance of Social Hygiene Day, February 5, in the Chamber of Commerce.

Agencies sponsoring the Social Hygiene Day observance were the Rochester Health Bureau, the University of Rochester, the District Office of the State Department of Health, the Monroe County Medical Society, the Tuberculosis and Health Association, and the Junior Chamber of Commerce.

The national observance is sponsored by the American Social Hygiene Association, a voluntary health organization which works in close cooperation with the Army, Navy, U.S. Public Health Service, and other similar units of the federal and state governments.*

New York County

The New York Heart Association, formed thirty years ago to study diseases of the heart, and, since 1926 a division of the New York Tuberculosis and Health Association, Inc., will resume the status of an independent organization on April 1, it was announced on January 26 at a dinner meeting in the Hotel Carlyle, New York City.

Announcement was made in a joint statement by Dr. J. Burns Amberson, president of the tuberculosis association, and Dr. Edwin P. Maynard, Jr., president of the heart association. The expansion of the program of the latter group, the statement said, made it inadvisable for both organizations to continue together.

Dr. Maynard also announced a campaign for $150,000 for the new association, to begin in the near future under the direction of Dr. Harold E. B. Pardee. The association will maintain offices at the New York Academy of Medicine, and the financial committee will have offices at 331 Madison Avenue.*

• • •

A second pint of whole, Rh-negative, type A blood left La Guardia Field by Army bomber on January 10 on its way to Alexandria, Egypt, where it provided a transfusion for a 15-year-old Greek boy. The first pint left this country on December 15, and reached Alexandria five days later, traveling without refrigeration.

Dr. Lester J. Unger, director of the Blood and Plasma Exchange Bank of the county society, said that this was thought to be the first time whole blood had been shipped without refrigeration more than two hundred miles. Dr. Unger said the blood was sent directly from the stock of the Blood and Plasma Exchange Bank at Post-Graduate Hospital. It was encased only in insulating material, and was accompanied by a sterile transfusion administration set.*

• • •

Tau Chapter of Nu Sigma Nu met for the annual Walter L. Niles Memorial Lecture on February 20, at 8:15 P.M., in the auditorium of the Cornell University Medical College. The speaker was Dr. E. Cowles Andrus, associate professor, Johns Hopkins University, and Chief, Division of Medicine, Committee on Medical Research, Office of Scientific Research and Development. Dr. Andrus' lecture was entitled "Wartime Medical Research."

• • •

New York University announced on January 29 the establishment of a division of physical medicine, financed under a $250,000 grant from the Baruch Committee on Physical Medicine. The new division, part of the university's College of Medicine, will specialize in research in physical and vocational therapy and preparation of doctors to rehabilitate both wounded war veterans and civilian disabled.

Last April 27 the ten-year grant of $250,000, which will yield a yearly income of approximately $30,000 to the division, was given to the university by the Baruch committee, which was organized in October, 1943, by Bernard M. Baruch to explore the possibilities of service in the field of physiotherapy.

To head the new division Harry Woodburn Chase, chancellor of the University, named Dr. George G. Deaver, director of the university's program for training technicians in physical therapy and medical director of the Institute for the Crippled and Disabled. He will have the title of clinical professor in charge of physical medicine.

The division will supervise the physiotherapy and occupational therapy services of Bellevue Hospital and will coordinate this work with the rehabilitation program of the Institute for the Crippled and Disabled, which is three blocks south of Bellevue on First Avenue.*

Hospital News

Improvements

For more than a year a committee appointed by the Boonville Kiwanis Club, consisting of Fred Pareria, Lyman P. Williams, Clayton A. Musser, Devere K. Merrill, and Joseph Sternberg, has been endeavoring to make arrangements whereby the building owned by the Dodge Memorial Hospital could be used for public purposes. The members of this committee have taken the matter up with State officials.

In January Mr. Williams, who has acted as counsel for the committee, received definite assurances from the Attorney General's office that if the Village of Boonville, through the Village Board, would accept the Dodge Memorial Hospital building and agree to use it for public or governmental purposes, this would meet with the approval of that Department.

Mr. Williams states that if the people of the Village of Boonville wish to have the village take over the Dodge Memorial Hospital building and complete it and use it for public purposes, it would appear that it could be done at this time. If it is done, it will result in the final solution of the problems connected with the hospital which have been confronting the community and its residents for the past several years.*

• • •

The board of managers of Rome Hospital, Troy, has under consideration a suggestion that illuminated signs be erected at the exit and entrance to the institution, Mrs. Myra Wheat, secretary of the board, informed aldermen last night. The suggestion for such a sign came from Alderman Alfred M. Hoehn.*

At the Helm

Mrs. Dana H. Grant, of Mt. Vernon, was unanimously elected a member of the board of managers of Mount Vernon Hospital, and presented to board members, by Arthur L. Zerbey, board president, at a meeting on January 15 at the hospital.

Mrs. Leon Mann was unanimously elected an honorary member of the board in recognition of her "distinguished service on the board and as a member of various committees over a period of thirty-two years." Mrs. Mann's term of office expires next month.*

• • •

Word has been received that Capt. Morris Schwartz, of Beacon, is now in full charge of the neuropsychiatric section of the 97th General Hospital in England.*

• • •

Four new trustees, choices of a nominating committee headed by Harold R. LaBonte, were elected by the staff of Tompkins County Memorial Hospital, Ithaca, on January 15. They were Walter N. Brand, Bernard M. Clarey, Arthur J. Keeffe, and Clifford L. Morgan. They succeed Joseph S. Barr, LaBonte, Lewis H. Durland, and Prof. E. Frank Phillips.*

• • •

The Tioga County General Hospital's board of directors re-elected all officers and chose three new members of the board on January 16 at the hospital.

The new directors are: John T. Slater and Harold C. Watrous, both of Waverly, and Herman Porter, of Lockwood. Re-elected directors were: Joseph J. Mullins, Earl C. Cooper, Berton J. Cotton, Floyd G. Doty, Edward W. Eaton, Myron L. Fisher, William E. Halstead, Luther C. Hardy, I. N. Peterson, and Verne A. Hicks.

Officers were all re-elected as follows: president, Arthur B. Stiles; first vice-president, Hon. Nathan Turk; second vice-president, Leonard R. Chubb; third vice-president, Jesse Hart; secretary, Luther C. Hardy; treasurer, Earl C. Cooper; executive committee, Mr. Stiles, chairman, Mr. Cotton, Hart I. Seely, Arthur S. Buckley, Mr. Hardy, Mr. Cooper, Mr. Eaton, Elwin H. Johnston, Floyd Beers, Clifford Dounce, and Dr. Harry S. Fish.*

• • •

John P. Gualtieri was elected president of the board of managers of the Rome and Murphy Memorial Hospitals, Troy, at the annual meeting of the organization at the institution on January 8. He succeeds Dr. Dan Mellen, who had been president for several years.

William Hughes was re-elected vice-president, and Mrs. Myra Wheat was returned as secretary.

President Gualtieri returned to the board as a member in December after an absence of a year, part of that time being spent with the Supreme Allied Headquarters in England.*

• • •

The resignation of Dr. Lester D. Bowman, of Jamestown, as City Physician, effective January 1, was announced on January 18 by Welfare Commissioner Carroll M. Hall at the regular meeting of the board.*

• • •

Five directors were elected to the Tarrytown Hospital Board of Directors at the annual meeting on January 15, and the entire group of officers was re-elected at the regular meeting which followed.

Officers re-elected were Frederick P. King, president; Ellery L. Wright, vice-president; Wallace Odell, secretary; John Hunter, treasurer.

Elected as directors for the class of 1947 for three-year terms were John J. Foley, Frederick P. King, Mrs. Charles Tod Newberry, Duncan Sutphen, Jr., and Julian Street, Jr. Other new members on the board, elected at the previous meeting, include Robert M. Akin, Jr., and Ellis D. Slater, class of 1946.*

FIRST NATIONAL PUBLIC HEALTH NURSING DAY

Hundred
celebrated
Day, Janu
Your Publi
Does" The purpose was to focus attention on public-health nursing as a service for everyone and to increase public understanding of the part played by the public-health nurse in helping build better health for family, community, and nation

In a message issued in connection with this observance, Dr Thomas Parran, Surgeon General, United States Public Health Service, called attention to the fact that nursing service is needed to translate into practice almost every phase of public health Child hygiene, maternity service, venereal disease control and tuberculosis control, industrial hygiene, and even home and community sanitation programs are only a few of the services which, if they are to function effectively, must have the guidance and assistance of nurses To quote

"Although public health nursing originated because there was need for professional nursing care of the sick on a visit basis in the homes, some of our public-health administrators have lost sight of that important public-health nursing function Prevention and cure of disease are two sides of the same problem They are not two separate problems From the beginning public-health nurses have been concerned with the total health situation of the family, including sickness care, disease prevention, and health promotion The whole public health profession, including hospital and sanatorium administrators, must share this same point of view if optimum health is to be obtained for all during the postwar period"

In setting aside January 26 as Public Health Nursing Day for America, Doctor Parran added, health administrators and all other friends of nursing should dedicate themselves to promote

(1) The extension of public-health nursing services so that there shall be enough qualified nurses to meet the needs of all people, (2) A plan for the payment and distribution of those services on the basis of need, not on the ability of the individual to pay; (3) The establishment of employment policies which will insure qualified nurses full employment, adequate compensation and the security incident to retirement benefits —*Health News, Dec 25, 1944*

COT-TAR
PIX-LITHANTHRACIS 5%

- Suitable in exudative and chronic eczema—particularly in children's eczema.

[Continued from page 552]

A. Robert Munro was elected president of the Knickerbocker Hospital, New York City, at the annual meeting on January 16.*

• • •

Arthur J. Burch has been re-elected president of the Leonard Hospital, Troy, Board of Directors at a corporation meeting at the McKean Staff House.

Charles C. Freihofer was named vice-president; Henry J. Eckert, secretary; and Charles H. Mason, Jr., treasurer. Five of the six directors were retained with five-year terms, including R. C. Reynolds, F. E. Draper, Jr., Charles H. Mason, Jr., H. M. Grout, and Chester S. Millhouse.

John Clark was chosen to succeed the late Arthur B. Cobden, long a member of the board. Yearly reports were read and approved.*

• • •

Alexander C. Nagle, of Scarsdale, was re-elected president of the White Plains Hospital Board of Governors at the executive session which followed the annual meeting of the Hospital Association on January 18 in the clinic rooms. Others re-elected were A. J. Purdy, Paul Fox, and Edward M. West, vice-presidents; Otto C. Jaeger, secretary; and Everett J. Penny, treasurer.

Mr. Nagle presided at the association session. Committee reports were given and Dr. Edwin G. Ramsdell, chief of staff, supervised the presentation of panel medical reports. Allan C. Stevens was elected to the board of governors to fill the vacancy left by the resignation of George F. Thomas. The term expires December 31, 1947. Re-elected for another three years were Mr. Fox, Mr. Purdy, and Mrs. James N. Hynson of Scarsdale. It was reported that James R. Stevenson had resigned from the board during the year.*

• • •

Charles L. Davis, Frank H. Andrews, and Lt. Col. E. Boyd Fitzpatrick were re-elected to the Board of Directors of Olean General Hospital for the term expiring in January, 1948, at the forty-fourth annual meeting of the hospital held on January 16 at the supervisors' residence.

Following the meeting the board elected the following officers for the ensuing year: Allan B. Williams, president; Mr. Davis, vice-president; Mr. Andrews, treasurer; Miss Dorothy V. Weston, secretary; and Miss Catherine M. Songster, assistant secretary.

The present medical staff of the hospital was reappointed for the current year. It was noted that fourteen doctors on the staff are at present in war service.*

• • •

Resignation of Dr. Ursula K. Arnsdorff as a resident physician at General Hospital was announced at a meeting of the Board of Estimate and Apportionment.*

• • •

Dr. J. Lewi Donhauser was elected chairman of the attending staff of Albany Hospital at a meeting on January 23 at the hospital.

Also elected were: vice-chairman, Dr. Lyle A. Sutton; secretary, Dr. Arnold W. Pohl.

• • •

Reginald G. Coombe, vice-president of the Central Hanover Bank and Trust Company, has been elected president of the board of managers of Memorial Hospital, New York City. Alfred P. Sloan, Jr., chairman of General Motors Corporation, was elected to the board. Mr. Coombe succeeds Harry Pelham Robbins, president since 1933, who will continue as a board member.

• • •

After serving ten years as one of the Herkimer County coroners, Dr. Fred C. Sabin, of Little Falls, has submitted his resignation to Governor Dewey, and has been sworn in as county home physician and medical consultant to Welfare Commissioner William Dise.

The new appointment was made by Dise to replace Dr. L. L. Kelley of Middleville, who has been unable to continue his duties because of ill health.

It is understood that an appointment to fill the unexpired term of Dr. Sabin as coroner will be made by the governor.*

Newsy Notes

Departing from their usual custom of holding annual dinners at different dates, the Cayuga County Medical Society and the Auxiliary, City Hospital staff, and Mercy Hospital staff combined this year for a banquet at the Osborne Hotel. Following the dinner, E. D. Vandeboncoeur, radio news commentator, addressed the doctors and their guests on phases of the World War of special interest to them. Several Cayuga County medical men now in military service were present, including Dr. Barnes, Dr. Charles T. Yarington, Dr. Joseph Graceffo, and Dr. Frank A. Namoc, a dentist. Also present as guests were wives of some of the Cayuga County physicians now in the service.

• • •

Early action is expected to be taken by Congress on the Joint Resolution providing for the leasing of the former Neponsit Beach Hospital for Children, Queens, by the U.S. Public Health Service, for a hospital for merchant marine patients. Negotiations are reported to be near completion.

The proposal, which has had the approval of Surgeon General Parran of the U.S. Public Health Service, the Federal Security Agency, the Federal Board of Hospitals, and the Federal Budget Director, will provide the Rockaways with its first large government supervised hospital.

• • •

Massena Memorial Hospital in its first year of operation admitted 1,433 patients, and throughout 1944 had an average of 38 plus patients daily, Miss Mildred Higgs, R.N., superintendent, reported on January 12.

Miss Higgs' report covers the period from January 4, 1944, the day that Massena's new hospital opened, to January 1, 1945.

ANESTHETIC CASUALTIES

The struggle to eliminate anesthetic deaths by more skillful use of a wider variety of agents is as old as anesthesia itself. It was first directed to chloroform, later to more precise use of newer agents which science devised for specialized employment. Undoubtedly each of these newer agents excels in certain definite conditions in spite of its increased hazard. Likewise, though cesarean section affords a relatively safe method of delivery where normal labor is contraindicated, no obstetrician, disregarding its higher mortality, would adopt this operation for routine delivery. Is not the same principle applicable to anesthesia? Safety rather than preference or convenience should determine the choice of anesthetic agent.

Judging from recent reports by Gillespie, Waters, Hanson, and Stealy, Elam, and the Medical Department of the U.S. Army, the frequency of anesthetic accidents is altogether too high. According to Elam's conclusions,[1] it were better to have borne the ills we had with chloroform than to have flown to others that we knew not of. He cites various statistics which show a mortality of 0.25 to 0.5 per cent charged to spinal anesthesia, with double the rate for local over general anesthesia, and with barbiturates leading the list. The U.S. Army found that the death rate attributable to pentothal was six times higher than that of all other anesthetic agents. Efficient though cyclopropane may be, Flagg says of it, "Let us look on cyclopropane as chloroform dispensed in gaseous form, under pressure."

At the recent American Medical Association meeting in Chicago the Section on Anesthesia took a step that should be most helpful in reducing these anesthetic casualties. Basing its action upon experience of groups in Philadelphia and Cleveland, organized to study reports on anesthetic deaths, the Section recommended that the American Medical Association favor formation of similar groups throughout the country. The object of such studies is educational rather than critical. Among obstetricians a similar attack has contributed definitely to reduction of maternal mortality. Hingson suggests that recommendations for changes in procedure should be based on at least fifty cases. In groups organized to study reports of all anesthetic deaths discussion will elicit the experience of the entire group. In this way the individual anesthetist would benefit from combined experience with large numbers of cases. Routine administration of anesthetic agents with attending increased mortality would therefore be avoided. Safety should surmount convenience.—*Editorial by Howard Dittrick, M.D., in Anesth. & Analg., Sept.-Oct., 1944*

Woman's Auxiliary

To the Medical Society of the State of New York

County News

Broome County. The January meeting of the Woman's Auxiliary of the Broome County Medical Society was held at Lourdes Hospital, Binghamton. Mrs. Manuel M. Monserrate presided at the business session.

Mrs. William E. Low, program chairman, introduced the three speakers of the evening. Lt. Comdr. John Kane, of the Navy, home on leave, gave an account of his experiences in the Pacific Theater. Life aboard an aircraft carrier was described by Aviation Ordnanceman Second Class Lawrence Littig, home after fifteen months aboard a carrier in the Pacific. Pfc. Jack Mitchell, USMC, told of conditions in the South Pacific war zone. Thomas Judge, a student in Johnson City High School, sang two solos, and refreshments were served.

The committee in charge was headed by Mrs. Mark Williams, assisted by Mrs. John Burns, Mrs. William Behan, Mrs. Waldemar Boldt, Mrs. Albert Baumann, Mrs. Ralph Goudey, Mrs. Milton Carvalho, Mrs. Harold W. McNitt, Mrs. John D'Arecca, and Mrs. Leonard J. Flanagan.

Columbia County. The quarterly luncheon meeting of the Woman's Auxiliary to the Medical Society of Columbia County was held on January 23 at the General Worth Hotel, with Mrs. Hugh G. Henry, of Germantown, presiding.

Following the luncheon, Mrs. Henry presented Mrs. Luther H. Kice, of Garden City, chairman of legislation of the Woman's Auxiliary to the American Medical Association, who gave a most vigorous and enlightening talk on the duty of members of medical auxiliaries to combat socialized medicine, and in all ways to acquaint themselves with all legislation appertaining to the practice of medicine. Saying that the welfare of man is the work of the medical profession, the speaker stressed the great work the "medics" are doing in the present war, work in which there is no glory, work which is often dirty and hard, but work which results in the saving of ninety-seven out of every one hundred wounded men.

A brief business session followed Mrs. Kice's address. Mrs. Henry appointed the following nominating committee: Mrs. H. J. Noerling, Mrs. R. L. Bowerhan, and Mrs. J. L. Edwards. The Auxiliary voted to send its annual contribution of $10 to the Physician's Home in New York City.

Erie County. A special meeting of the Board of Directors was called by the President, Mrs. William Rennie, on January 9 in the board room of the Medical Society of the County of Erie, to outline plans for the new year. The first regular meeting of the Board of Directors was held at 10:30 A.M. on January 30, in the same room. We are very grateful for the opportunity of holding our meetings there.

The Red Cross Knitting Group was entertained at a luncheon on January 18 in the home of Mrs. Fraser D. Mooney. Cohostess was Mrs. Arthur F. Glaeser. Six afghans have been completed during the past year and two more are nearing completion. The next hostesses will be Mrs. Jesse G. Levy and Mrs. Fred S. Hoffman. We hope to triple the number of afghans this year, under the guidance of Mrs. Louis Fuchs, chairman of the War Service Committee, and Mrs. Walter L. Machemer.

Thank you, members of the Erie County Medical Society, for your cooperation in helping us triple our quota in the Sixth War Loan Drive.

We could not have accomplished this without the assistance of the Auxiliary members who were in attendance at the Bond Booth in the Buffalo General Electric Building. We salute the women who did the work. Mrs. Walter Goodale, chairman, Mrs. Francis O'Gorman, cochairman, Mrs. George E. Slotkin, Mrs. Joseph W. Madden, Mrs. Arthur C. Hassenfratz, Mrs. Harold B. Johnson, Mrs. Kenneth G. Jahraus, Mrs. Lee R. Sanborn, Mrs. Louis A. Kaiser, Mrs. John D. Naples, Mrs. James G. Fowler, Mrs. Wilhelm H. Brauns, Mrs. William H. Jones, Mrs. Lawrence J. Radice, Mrs. Frank N. Potts, Mrs. Harry C. Guess, Mrs. John A. Post, and others.

The war is not over and we are continuing to man the booth for the duration and six if necessary. This is a vital duty on the home front, and let us be generous in our cooperation to our new chairman, Mrs. Lee R. Sanborn, and cochairman, Mrs. Frank N. Potts. They have a very workable plan whereby the members volunteer a half day a week for one month out of the year. This isn't too much to ask of any member. Some members work all through the year.

In this way, the booth will be covered at all times and at the end of the year it will give us all an opportunity to say, "I helped in the war effort."

The first regular 1945 meeting of the Woman's Auxiliary to the Medical Society of the County of Erie was an introductory luncheon in the Chinese Room of the Hotel Statler, at 12:30 P.M. January 30, honoring the New York State presidents, Dr. Herbert H. Bauckus and Mrs. Carlton E. Wertz, the county president, Dr. Abraham H. Aaron, and the other members of the Advisory Council, Dr. Louise Beamis Hood, Dr. Alfred H. Noehren, and Dr. Arthur F. Glaeser.

Hostesses were the past presidents of the County Auxiliary, Mrs. Arthur F. Glaeser, Mrs. Harold B. Johnson, and Mrs. Patrick J. Hurley. The chairman of the House, Mrs. Frederick E. Sperry, had as her aides Mrs. Daniel Stedem and Mrs. John A. Metzen.

After the luncheon there was a preview of Maj. Clark Gable's recent film, "Combat America," and an introduction of the Auxiliary's new Board of Directors.

Nassau County. The regular meeting was a joint meeting with the Nassau County Medical Society at Mercy Hospital, Rockville Centre, on January 30 at 9 P.M. Dr. Charles Albert Gordon, F.A.C.S., gave a report of the Maternal Welfare Committee of Kings County, and Dr. George Borden Granger, F.A.C.S., gave a report of the Maternal Welfare Committee of Nassau County. The Auxiliary served refreshments after the meeting.

IN IRON-DEFICIENCY ANEMIA

The blood in iron-deficiency anemia is markedly benefited by Copperin administration: hemoglobin percentages quickly rise; red blood cells increase in quantity and improve in quality.

Due to the action of the catalyst, copper sulphate, the amount of iron ammonium citrate per capsule is reduced to only 32 Mgm. But as ALL the iron is made available, maximum therapeutic effect is obtained. Copperin does not stain teeth or irritate the gastrointestinal tract and is water soluble. Prescribe Copperin "A" for adults, Copperin "B" for children.

EMERGENCY CALL!

MEDICS BAIL OUT TO AID CUT-OFF U.S. BATTALIONS

SUPREME HEADQUARTERS, Allied Expeditionary Forces—By parachute and by glider, Army surgeons went to the aid of the gallant garrison of beleaguered Bastogne.

The surrounded lost their only hospital in one of the first German attacks. With more than 800 wounded, the commanding officer radioed for medical aid. The response came immediately. Medics and medical supplies went in by parachute, by glider, and in Piper Cub planes.

FROM Bastogne to Leyte, the story is being repeated over and over again—of Army doctors, braving the battle hazards of the front line, risking *their* lives to *save* lives.

Emergency call? *Every* call is an emergency call to these *heroes in white.* And with the Army doctor, as with the fighting men they care for, rest is often limited to a few moments of relaxation and a good cigarette. A Camel cigarette, more than likely, for Camels are the favorite with men in all the services, according to actual sales records.

3 ADVANTAGES OF PRIVINE*

1. PROLONGED VASOCONSTRICTION

Privine usually provides symptomatic relief from nasal congestion for 2 to 6 hours without reapplication.

2. SMALL DOSAGE

Only 2 to 3 drops of Privine are needed for prompt and prolonged vasoconstriction.

3. PHYSIOLOGICAL RATIONALE

Privine is prepared in isotonic solutions strongly buffered to the same pH as the delicate nasal mucous membranes. It thus restores alkaline pathological secretions to normal acid range.

PRIVINE

(NAPHA[illegible])

DOSAGE: 0.1% for adults ; 0.05% for adults and children.

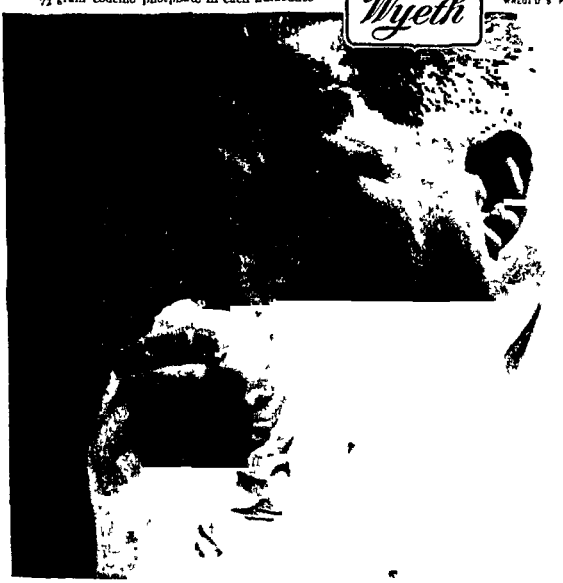
CETRO-CIROSE

MODIFIED

(WITHOUT CODEINE)

WYETH



AN EXCELLENT VEHICLE FOR ADMINISTERING ADDITIONAL MEDICATION

CETRO-CIROSE* Modified is an effective cough remedy that will also serve as an excellent vehicle for the administration of ammonium chloride, benzoin, etc., in cases requiring additional medication. Flavored with wild cherry and menthol, it is well received by children and other taste-conscious patients. Because it is free of sugar, Cetro-Cirose Modified can be used with the assurance that it will not upset the stomach.

EACH FLUIDOUNCE CONTAINS:	
Chloroform	1½ minims
Alcohol	1½ per cent
Fluidextract of Ipecac	1 minim
Glycerin	210 minims
Potassium Guaiacolsulfonate	8 grains
Sodium Citrate	18 grains
Citric Acid	6 grains
Flavored with Wild Cherry and Menthol	
SUPPLIED in pint and 1 gallon bottles	

ALSO AVAILABLE—Cetro-Cirose containing ½ grain codeine phosphate in each fluidounce

VAGINAL THERAPY SIMPLIFIED

A PRACTICAL NEW APPROACH THROUGH RESTORATION OF NORMAL ACIDITY

Investigators have shown that vaginal inflammation tends to interfere with glycogen metabolism in the epithelial wall . . . resulting in lowered acidity or even alkalinity (a condition favorable to the infection). Numerous controlled clinical studies* have demonstrated that proper acidification of the vaginal vault is often the *simplest and most direct form of effective therapy*

Aci-jel, a bland, water-dispersible, buffered, acid jelly provides a simple, yet highly effective treatment of nonspecific vaginitis, trichomoniasis, monilia vulvovaginitis, certain types of cervicitis, and following cervical conization or cauterization. The usual dosage is 5 cc. (applicator full) intravaginally before retiring and again in the morning, followed 8 hours later with a cleansing douche.

Aci-jel (available in 3¼ oz tubes with or without measured applicator) merits serious clinical trial in your own practice

THEOBROMINE SODIUM ACETATE
The ORIGINAL ENTERIC-COATED TABLET OF THEOBROMINE SODIUM ACETATE
Brewer
EFFECTIVE
in Coronary Artery Disease and Edema*

Clinical experience and carefully controlled studies in *humans* have definitely proven the value of Theobromine Sodium Acetate in treating certain Cardiovascular and Renal diseases, and the value of the enteric coating in permitting adequate dosage without causing gastric distress.

Supplied—in 7½ grains with and without Phenobarbital ½ grain; in 5 grains with Potassium Iodide 2 grains and Phenobarbital ¼ grain (cost approximately $1.50 per bottle of 100 tablets); and in 3¾ grains with and without Phenobarbital ¼ grain (cost approximately $1.00 per bottle of 100). Capsules, not enteric coated, are available in the same potencies for supplementary medication.

*Literature giving confirming bibliography, and physicians samples will be furnished on request.

Anti-Gravity Combat Unit For The Prevention Of Pilot's "Blackout"

* *Developed By The Designers Of*

SPENCER SUPPORTS

Solution of the blackout problem involved physiological research of marked interest to the medical profession. With the permission of the Army Air Force Medical Services, we are offering to the medical profession a reprint from *The Air Surgeon's Bulletin* of January, 1945.

* In the development of the combat unit we had the cooperation of the following:

The Aero-Medical Laboratory, and the Proving Ground Command of the Army Air Forces; the Medical Research Section of the Bureau of Aeronautics of the United States Navy; the National Research Council's Committee on Acceleration, members of which are associated with the Mayo Clinic, Johns Hopkins, Banting Institute, Yale University—and other medical and aviation authorities.

We are happy that our long experience with the basic engineering and physiological principles involved in the designing of Spencer Supports enabled us to provide such a valuable aid for our Air Forces.

CAVENDISH PHARMACEUTICAL CORP. • 25 West Broadway • New York 7, N. Y.

Quickly Relieved by Threefold Non-Narcotic Action of

Pavatrine
with
Phenobarbital

The new Searle Research Development—Pavatrine—is unique among spasmolytic agents by reason of its combined *neurotropic* and *musculotropic* actions.

To this has been added the mild, *central nervous sedation* of Phenobarbital to secure effective symptomatic relief in—

Gastrointestinal spasm (the "irritable bowel")
Uterine hypertonicity of dysmenorrhea
Urinary bladder spasticity

Each sugar-coated tablet contains 125 mg. (2 gr.) Pavatrine (Searle) with 15 mg. (¼ gr.) Phenobarbital. Supplied in bottles of 100 and 1000.

G. D. SEARLE & CO., Chicago 80, Illinois.

Pavatrine is the registered trademark of G. D. Searle & Co.

SEARLE

RESEARCH IN THE SERVICE OF MEDICINE

Announcing

INCREASED POTENCY

..For greater therapeutic effect

Now you can abundantly provide all the factors of the B Vitamin for severe "B" depletion—with Vitamin "B" Soluble (Walker). The potencies of Thiamin, Riboflavin and Niacin have been doubled and the fortifying Vitamin C has been trebled.

Vitamin "B" Soluble (Walker) is derived from brewers yeast. It therefore contains various known and unknown factors that are only found in the natural source.

The added Vitamin C gives marked biologic assistance to Vitamin B —a fact which has been clinically manifested in improved pathology of the upper respiratory mucosa.

in

BILIARY STASIS

A. SYMPTOMS OF DYSPEPSIA
   1. Fat intolerance
   2. Discomfort after meals
   3. Eructation
   4. Epigastric Distention
   5. Nausea
   6. Coated tongue
   7. "Billiousness"

B. TENDENCY TOWARD CONSTIPATION

C. PAIN
   1. Tenderness in right upper quadrant
   2. Accentuated after meals

EVEN in the EARLIEST STAGES . . . OF HEPATOBILIARY INVOLVEMENT

Impairment in bile flow, even in its earliest manifestations, calls for prompt corrective measures. While minor impairment may indicate only incipient hepatic dysfunction, the biliary stasis and engorgement which may ensue, will tend to depress liver function still further. Since a cycle of continuing deterioration is thus apt to become established, it is the more important that adequate bile flow be rapidly reestablished.

Appreciated for its remarkably low toxicity. Contraindicated only in complete obstruction.

Decholin (chemically pure dehydrocholic acid) presents the specific means of increasing the flow of bile (by as much as 200%), leading to an outpouring of thin liver bile, promoting drainage of the intra and extrahepatic bile passages.

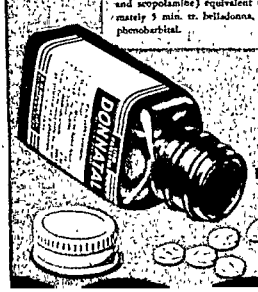
Donnatal RELIEVES SPASM WITH TENSION

In spastic disorders of functional origin—when the chief aim of therapy is to provide both central and peripheral action *with safety*—Donnatal may be employed with utmost confidence.



The outstanding efficacy of Donnatal is the result of a perfectly balanced combination of the principal belladonna alkaloids (hyoscyamine, atropine and scopolamine), in fixed proportions, together with phenobarbital. Thus Donnatal provides:

1. The advantages of the natural belladonna alkaloids *without toxicity.*
2. Effective *non-narcotic* sedation.
3. Marked pharmacologic potency with small dosage at *notably less cost.*

The synergetic implementation of Donnatal makes it an ideal antispasmodic and sedative in a wide range of spastic disorders—such as spasm incident to gastric and duodenal ulcers, pylorospasm, spastic constipation, urogenital spasm, cardiospasm, autonomic nervous disturbances, respiratory disturbances, Parkinsonism, vomiting of pregnancy, and other spastic manifestations.

AVAILABLE: In bottles of 100 tablets.

FORMULA: Each tablet contains belladonna alkaloids (hyoscyamine, atropine and scopolamine) equivalent to approximately 5 min. tr. belladonna, plus ¼ gr. phenobarbital.

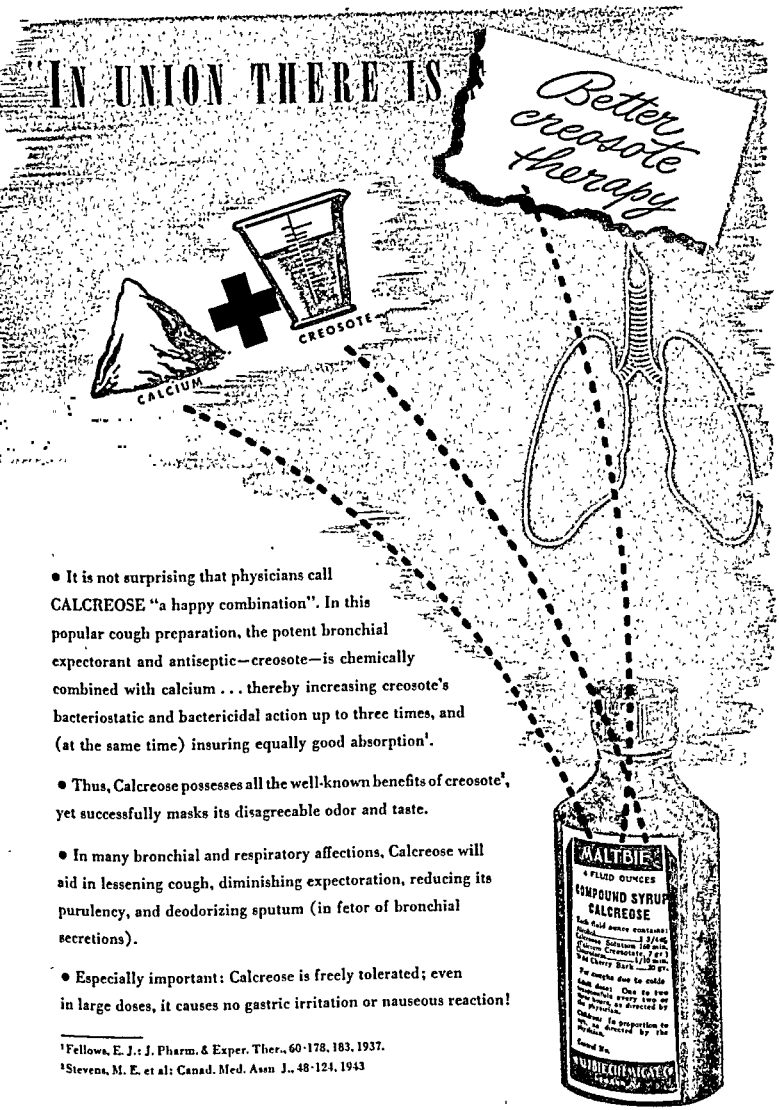
CAMP Belt for Inguinal Hernia

Belt with pad in place

Camp Spring Pad
(Patented)

Belt fitted, adapted to all types of build

IN patients with indirect inguinal hernia of small or moderate size, this belt with pad has proved successful in many instances in holding the hernia within the abdominal cavity. The comfort of a *belt* about the pelvic girdle is greatly appreciated by the patient.



The CAMP adjustable spring pad for use with the belt is equipped with prongs of piano wire. The strong flexible prongs fit firmly in the casings of the belt. Pads are available in varying shapes and depths.

The CAMP adjustment of the belt courses along the groin over the pad, hugging it in and up for the protection of the internal ring.

Surgeons who wish some protection over the area after operation will find this belt of particular advantage because the adjustment allows varying degrees of firmness about the lower abdomen.

"IN UNION THERE IS

• It is not surprising that physicians call CALCREOSE "a happy combination". In this popular cough preparation, the potent bronchial expectorant and antiseptic—creosote—is chemically combined with calcium . . . thereby increasing creosote's bacteriostatic and bactericidal action up to three times, and (at the same time) insuring equally good absorption[1].

• Thus, Calcreose possesses all the well-known benefits of creosote[2], yet successfully masks its disagreeable odor and taste.

• In many bronchial and respiratory affections, Calcreose will aid in lessening cough, diminishing expectoration, reducing its purulency, and deodorizing sputum (in fetor of bronchial secretions).

• Especially important: Calcreose is freely tolerated; even in large doses, it causes no gastric irritation or nauseous reaction!

[1]Fellows, E. J.: J. Pharm. & Exper. Ther., 60:178, 183, 1937.

"FOR ALL PATIENTS IN NEED OF IRON

it is desirable to use a compound which gives good results with the least discomfort."*

FERGON rarely causes gastric distress even when taken before meals, for its low degree of ionization makes it virtually non-astringent and non-irritating. Ferrous gluconate is utilized with greater efficiency as demonstrated by clinical comparison with other iron compounds.*

Fergon

Ferrous Gluconate Stearns

FOR IRON DEFICIENCY

SUPPLIED as 5% elixir, bottles of 6 fl. oz. and 16 fl. oz.; 2½ grain tablets, bottles of 100, 5 grain tablets, bottles of 100, 500, and 1000

Frederick Stearns & Company

Division

DETROIT 31, MICHIGAN

NEW YORK • KANSAS CITY • SAN FRANCISCO • WINDSOR, ONTARIO • SYDNEY, AUSTRALIA • AUCKLAND, NEW ZEALAND

FACTS ABOUT FERGON

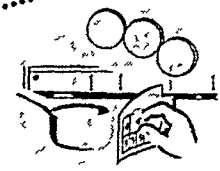
FERGON is *improved* ferrous gluconate Prepared by a special Stearns process and stabilized by an excess of reducing agent, it contains no more than 1/7% ferric iron

NON IRRITATING because of its low degree of ionization, Fergon is rarely associated with gastric distress Hence it may be administered before meals, thereby facilitating maximum absorption.

MORE EFFICIENT utilization of iron is demonstrated in clinical studies comparing ferrous gluconate with other iron salts It is readily soluble throughout the entire pH range of the gastro-intestinal tract.

INDICATED in the treatment and prevention of anemias due to iron deficiency; especially valuable in patients who do not tolerate other forms of iron.

DOSAGE: Average dose for adults is 3 to 6 tablets (5 gr.) or 4 to 8 teaspoonfuls elixir daily; for children, 1 to 4 tablets (2½ gr.) or 1 to 4 teaspoonfuls elixir daily



FURTHER FACTS FOR YOUR REFERENCE FILE AND CLINICAL SAMPLES WILL BE GLADLY SENT ON REQUEST

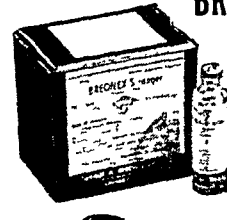
TRADE MARK FERGON—REG. U. S. PAT. OFF.



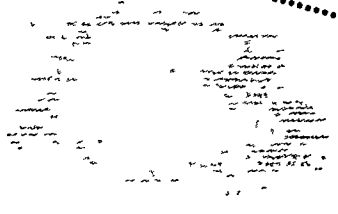
As is commonly observed by physicians, persons with one deficiency syndrome will likely have associated deficiency diseases, these deficiencies often being related to the vitamin B complex group. And, too,

the clinical picture of hypovitaminosis is generally marked by an inadequate diet, because of reasons often uncontrollable, such as vitamin losses from excessive cooking, improper storage, transportation, point rationing, and from high costs of food. However,

fatigued, listless patients with ill-defined symptoms involving nerves and general metabolism have been less of a problem since forceful vitamin B complex is readily available. Therefore, we suggest the physician's versatile co-worker—vitamin B complex-Breon, in three convenient forms—

BREONEX-STRONGER

In vials for various doses intramuscularly. Each cc contains thiamine 25 mg., riboflavin 2.5 mg., pyridoxine 2 mg., nicotinamide 100 mg.



BECAPLETS

compressed in the shape of capsules and sugar coated; each caplet contains thiamine 1 mg., riboflavin 1 mg., pyridoxine 0.03 mg., nicotinamide 6 mg.

BECOMCO

A potent liquid, palatable as a chocolate sundae. Each 5 cc contains: thiamine 3 mg., riboflavin 2 mg., nicotinic acid 10 mg., pyridoxine 1.5 mg., pantothenic acid 1 mg.

Does Tampax eliminate the problem of menstrual odor?

"THE ANSWER IS *Yes*"

Clinical investigators have shown that internal protection (as afforded by TAMPAX) serves to abolish objectionable odor . . . by absorption of the flow *before* it becomes exposed to air and can suffer consequent decomposition.[1,2] For "menstrual blood taken directly from the interior of the uterus has no odor."[4]

Primarily, TAMPAX meets *all* the requirements of modern menstrual hygiene — since (as one specialist summarizes) "the evidence is conclusive that the tampon method of menstrual hygiene is safe, comfortable and not prejudicial to health..."[3]

Indeed, so comfortable is "flat expansion", provided only by TAMPAX, that many women are hardly aware of its presence in situ.[1] Welcome freedom from external bulkiness, vulval irritation or chafing from perineal pads, allows the patient a wider range of activity during the period. An individual applicator permits easy insertion, and a moisture-resistant cord facilitates dainty removal.

TAMPAX is available in three sizes: "Super", "Regular" and "Junior", with absorptive capacities of 45-cc., 30.3-cc. and 20-cc. respectively. Use coupon below for professional samples.

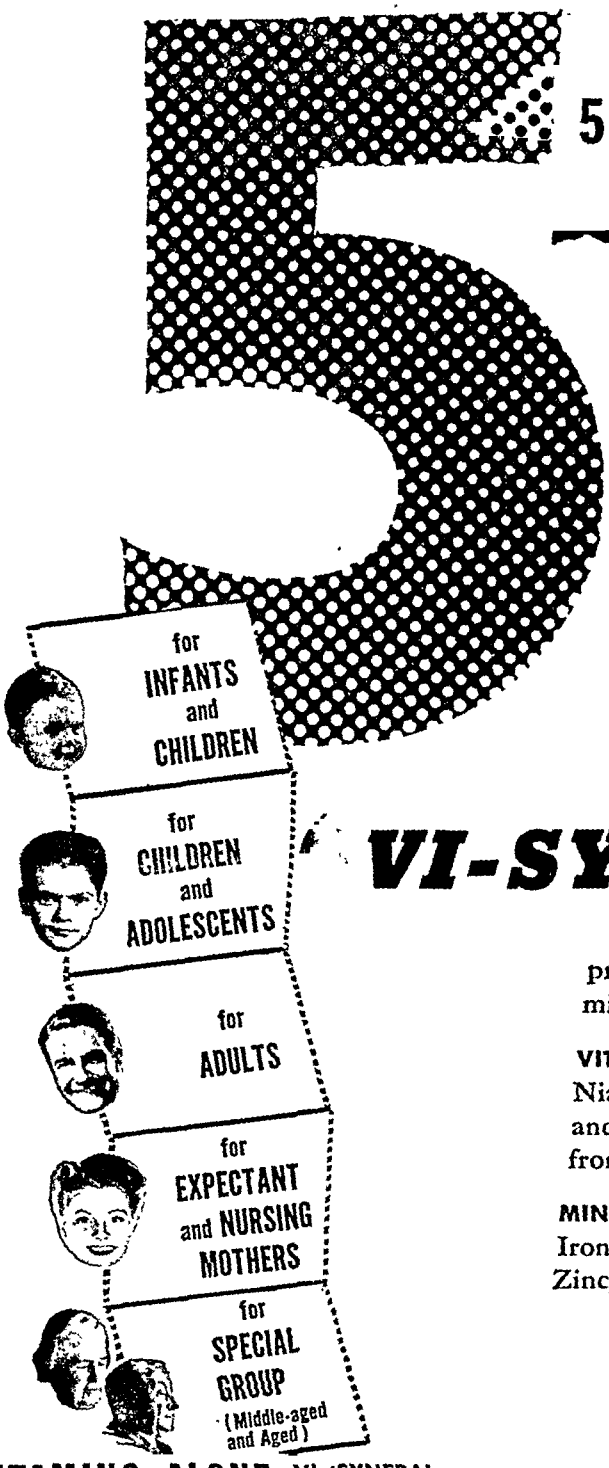
THE EMPIRE STATE'S CONTRIBUTION TO THE MEDICAL PROFESSION

WHEN THE *Restorative* POWERS OF TISSUE MUST BE AUGMENTED

In the management of burns and non-infected or infected indolent wounds, Morruguent Ointment has proved of highly beneficial influence on healing. Based on the unsaponifiable active principles present, Morruguent is 25% stronger than cod-liver oil, U.S.P. This greater content of the vitamin-bearing fraction, to which the stimulant influence on wound healing is attributed, accounts for the greater therapeutic value for which Morruguent has been acclaimed by so many physicians.



MORRUGUENT

Wound odor disappears, necrotic material is liquefied, granulation tissue fills the wound, epithelization begins early, scarring is minimized. Morruguent Ointment is applied directly onto the wound, gauze covered, and the area lightly bandaged. Supplied in 2-oz. collapsible tubes, and in 1-lb. and 5-lb. jars.

POWER.....

● The analgesic power of DEMEROL hydrochloride ranks between morphine and codeine, but carries with it considerably less risk of addiction. The majority of patients do not acquire tolerance. The incidence of euphoria produced by DEMEROL hydrochloride, in the presence of pain, is only 10 per cent. Furthermore, respiratory depression from DEMEROL hydrochloride is very uncommon, and the drug has no constipating effect.

Spasmolytic and sedative action

In addition to its marked analgesic potency, DEMEROL hydrochloride possesses spasmolytic action similar to that of atropine and papaverine, as well as mild sedative effects.

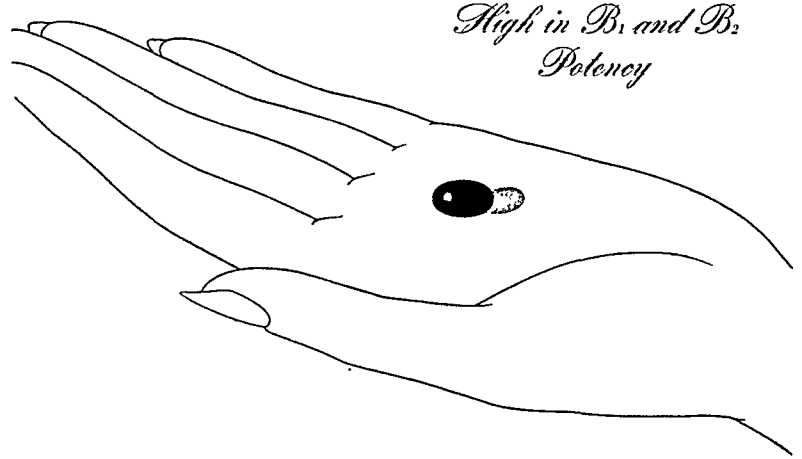
NITROBAR

IMPORTANT ACCOMPLISHMENTS in the treatment of essential hypertension:

1. gradual lowering of the blood pressure and a subsequent prolonged period of low pressure
2. relaxation of the patient's general nervous tension



The bismuth subnitrate (5 gr.) in Nitrobar is reduced in the intestine and thus provides a gradual stream of nitrite ions which relax the vessel walls and bring the blood pressure down in a long curve, maintaining this low level for a matter of hours.

The addition of phenobarbital ⅛ gr. together with ext. passiflora ½ gr. and ext. lupulus ½ gr. induces the "mental relaxation" necessary to relief of hypertension. Nitrobar Comp. is supplied in engestic coated red tablets. Caution: Use only as directed.

9 vitamins in one small capsule

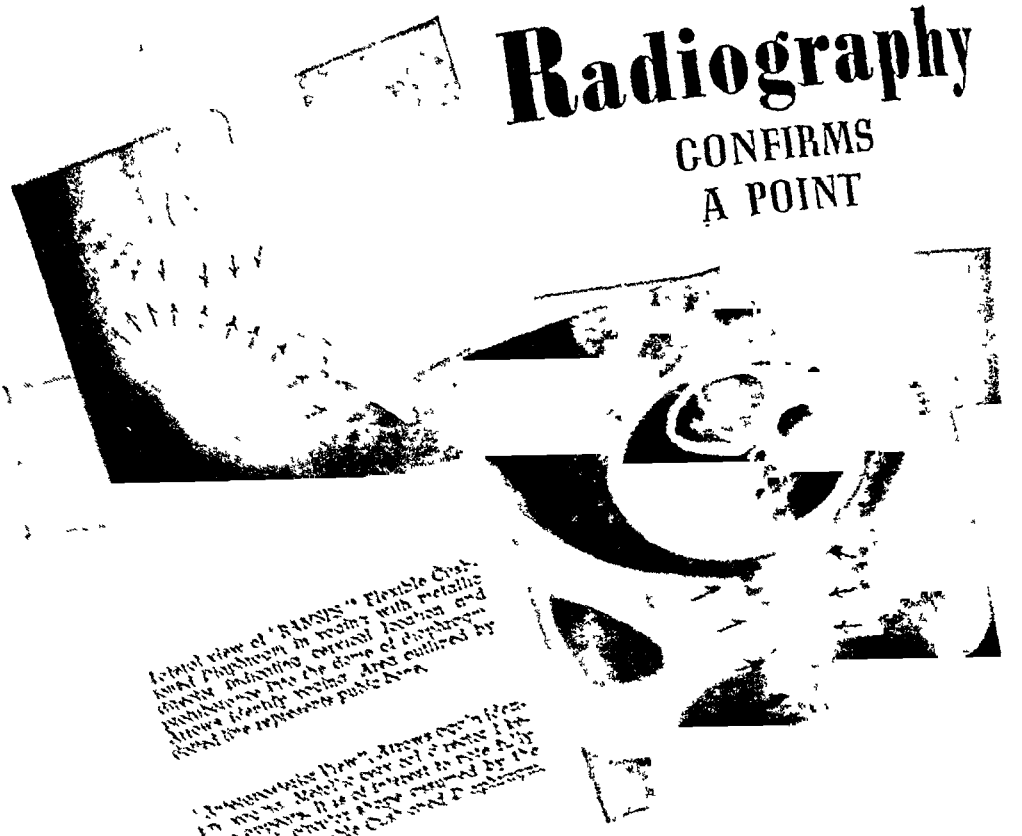
TRAPADIN IMPROVED is the only Nine-Vitamin Capsule preparation with vitamins B_1 and B_2(G) at high levels and in the A.M.A. Council accepted ratio of 1 to 2.

In resisting *multiple vitamin deficiencies* during and after anemia, pregnancy and various acute and chronic illnesses, Trapadin Improved Capsules are a valuable high-potency therapeutic supplement.

Trapadin Improved guarantees a high B_1 and B_2(G) intake in conjunction with the fat-soluble vitamins A, D and E, and the water-soluble vitamins C, PP, FF and B_6, thus being a particularly valuable adjunct for *speedy* restoration of optimum nutritional states.

Every Improved Trapadin Capsule provides the following:

Nine (9) Vitamins:



A:	5000 USP units Vitamin A
D:	1000 USP units Vitamin D
C:	75 mg. Ascorbic Acid
B_1:	5 mg. Thiamine HCl
B_2(G):	10 mg. Riboflavin
PP:	30 mg. Niacin Amide
FF:	3 mg. Pantothenic Acid
B_6:	1 mg. Pyridoxine HCl
E:	10 mg. Mixed Tocopherols

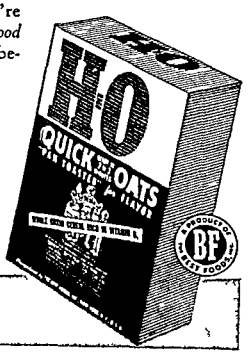
YOU know that whole grain oats lead all other cereals in valuable grain protein, that they lead all other cereals in fat content, that they have an edge on all other cereals in food energy, that they contain natural Vitamin B1, calcium, iron and phosphorus You know they're good in any well balanced diet, and one of the best foods to depend on in low cost diets

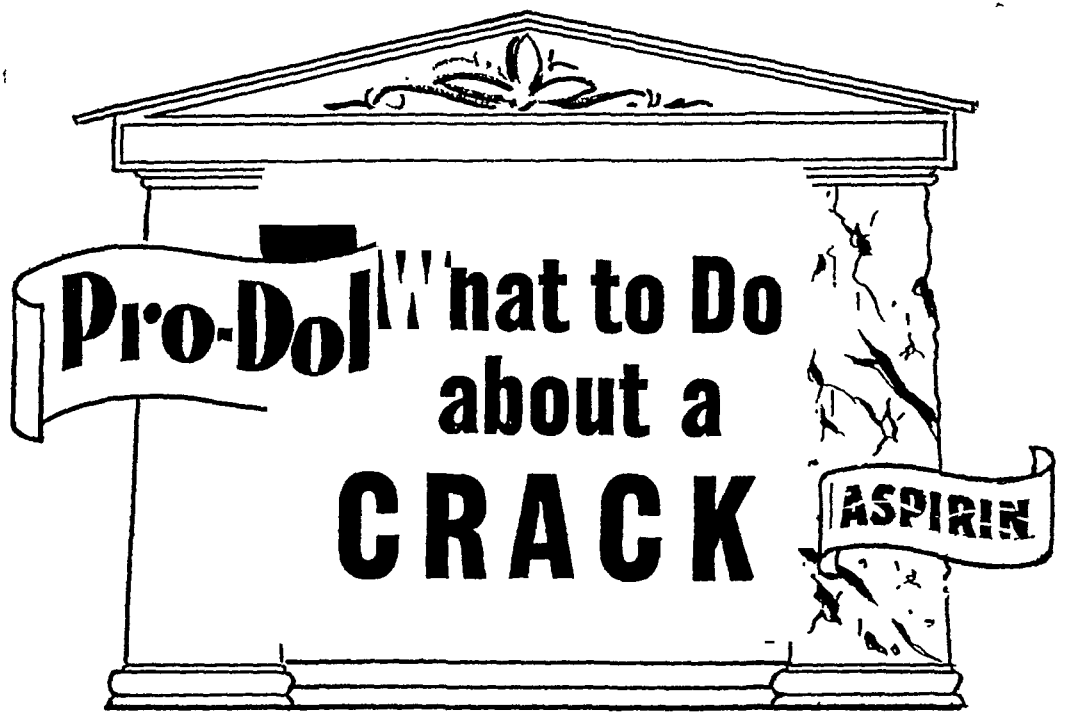


But do you know how good oatmeal can *taste?*

That's where H O Oats come in! Maybe you think of oatmeal as pasty and soggy Not H O! It's precision cut for fine, light, creamy texture Maybe you think of oatmeal as so bland only children can stay really satisfied with the taste Not H O! H O's toasted—*pan toasted* over the gentle, dry, slow heat of open fires to bring out a *delicious toasty taste, a teasing aroma,* and an appetizing color

H O's the kind of cereal grownups as well as youngsters can eat morning after morning and not get tired of it And that counts for a lot when you're recommending low-cost diets or just ordinary, sound diets—because you know you're recommending a *good* habit that can become permanent

- **Oatmeal leads all other whole grain cereals in proteins**
  Oatmeal supplies 64 grams of proteins per pound
- **Oatmeal leads all other cereals in fat content**
  Oatmeal supplies 7 4%
- **And oatmeal has an edge on all other cereals in food energy**
  Oatmeal supplies 1 720 calories per pound



Besides **generous supplies of Vitamin B1 niacin and nutritional iron**

And here's another treat: H-O *Old-Fashioned* Oats—slow cooking, hearty, rich in flavor.

The BEST FOODS, Inc.

88 Lexington Avenue, New York 16, N Y

Any aspirin will "crack". It will hydrolyze in the stomach to a large extent. *From the first moment of entry* salicylic and acetic acids are liberated. Left to themselves, these membrane-irritating acids often produce disagreeable symptoms of hyperacidity.

To the practitioner, whose use of aspirin for effective analgesia is subject to these conditions, ethically promoted PRO-DOL is offered.

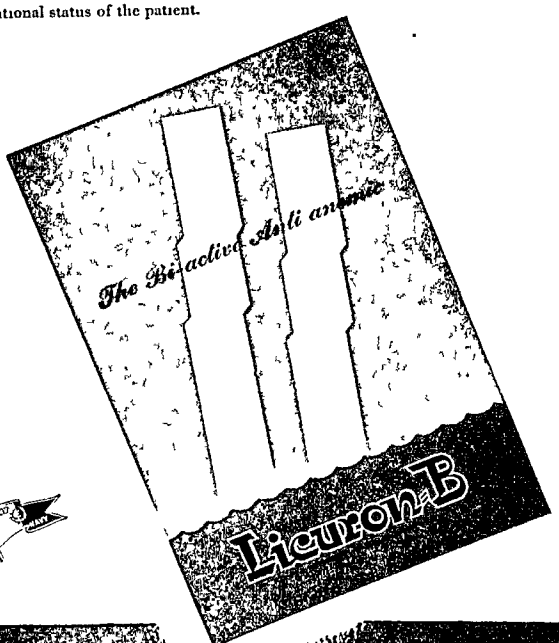
PRO-DOL *affords effective aspirin therapy buffered and insulated against side-effects of plain aspirin, without the disadvantages of alkalis.*

In PRO-DOL therapy 5 grains of aspirin are incorporated with 7½ grains of dried aluminum hydroxide gel in each full dose. As soon as they are formed, irritant acids are neutralized and adsorbed.

No adjuvants are required. PRO-DOL's balanced formula provides automatic correction irrespective of the total aspirin needed for pain relief. An exclusive feature insulates aspirin from gel inside each tablet until used.

DOSAGE: 1 or 2 tablets, repeated as required, for temporary relief of headaches, neuralgias, and muscular aches and pains.

HOW SUPPLIED: Boxes of 24 flavored tablets, each tablet individually protected in Sanitape.



Write today for professional samples and literature.

BI-ACTIVE ANTIANE

Hemoglobin-increase may not result in general health if complicating nutritional deficiencies remain untreated. LICURON-B provides the copper-iron ratio which is basic therapy in hypochromic anemia. Simultaneously, liver B-vitamins augmented by the crystalline vitamins, thiamine, riboflavin and niacinamide, raise the nutritional status of the patient.

LAKESIDE

Compatible companion for soap

A surface injury contaminated by dirt, or an unbroken skin in which an incision is to be made, requires a good scrubbing with soap and water before the application of a potent antiseptic. 'Merthiolate' (Sodium Ethyl Mercuri Thiosalicylate, Lilly) retains its bactericidal properties in the presence of soap, has prompt, well-sustained germicidal effect, and is compatible with tissue and body fluids.

Editorial

Standards of Medical Practice

There are now in the legislature awaiting action bills[1] which, in the opinion of the editors of this JOURNAL would lower the standards of medical practice in the State of New York. These bills permit the Board of Regents to reinstate a license for the practice of medicine of a person convicted of a felony if he has received a certificate of good conduct from the parole board.

The law governing the practice of medicine now permits the Regents to revoke the license of a person convicted of a felony under Section 1264, Article 48, of the Education Law. This is not mandatory. However, under Section 1263 it states, 'Any person who during the time his license to practice medicine shall be suspended or revoked, or who shall be convicted of a felony shall practice medicine, shall be guilty of misdemeanor." It is our understanding of the law that a person who is convicted of a felony, whether his license be revoked by the Regents or reinstated by them, would be guilty of a misdemeanor each time he practices. It is for this reason that the Regents, recognizing that the law is permissive in regard to the revocation of a license, have always revoked the license, as the person could not practice without committing a crime.

Section 1251 states in part as follows, " nor shall any person be licensed to practice under this article who has ever been convicted of a felony by any court, or whose authority to practice is suspended or revoked by the department." The same section states that "If a person convicted of a felony is subsequently pardoned by the governor of the state where such conviction was had, or by the President of the United States, the Regents may, in their discretion on application of such person, and on the submission to them of satisfactory evidence, restore to such person the right to practice medicine in this State."

It will be noticed from the above section that the Regents have the permission to restore a license on the pardon of the Governor or the President at the present time. This same section under the old Public Health Law gave the same permission but had the provisionary clause, "provided the felony was not in connection with the practice of his profession." It will be noted also,

[1] *Senate Int 60—Coudert* and *Assembly Int 67—Milmoe*

under this section of the law, that a person who has been convicted of a felony could not be admitted to the licensing examination or obtain a license for the practice of medicine. One of the requirements for admission to the medical licensing examination is evidence of good moral character. That in connection with the above requirement of the statute would prohibit a person who had been convicted of a felony from being licensed. It would appear, then, that we are gradually lowering standards for the practice of medicine in regard to a person who has been convicted of a felony. At first the Regents did not have the permission to restore a license if the felony had been in connection with the practice of medicine, even on full pardon. This law would seem to put the Regents in a difficult position, as these applications could be made to them on the basis of a certificate of good conduct from the parole board. It would mean that a convicted felon who had previously been licensed to practice medicine could obtain such a restoration when the person who had not been licensed could never obtain a license. The question also arises as to whether a physician who has been convicted of a felony could practice medicine without committing a crime even though his license has been restored, unless the portion of section 1263 mentioned above be amended.

While it does not appear probable that any considerable volume of applications to the Regents under the proposed change in the law would arise to disturb the normally somewhat placid course of their deliberations, who can say that it may not? The mere fact of the introduction of the bills is in itself an invitation to submit such applications, should they be passed. It seems to us to be unfair discrimination between physician-felons.

It may have been assumed by the proponents of the legislation that the physician who, before his conviction, had not been licensed, never intended to practice anyway. But in our opinion the argument would be scarcely tenable. Physicians, like anyone else, have a right to change their minds. A pardoned unlicensed felon should at least be accorded the privilege of applying for examination on a parity with the previously licensed felon—that is, if it seems desirable to have pardoned felons in the ranks of the profession in this State at all.

Circular No. 101 of the New York State Bar Association discusses a bill passed in the Senate and the Assembly as part of the current "rehabilitation" program of the legal profession whereby a lawyer disbarred for felony can be reinstated as a practicing attorney. In voicing disapproval of the measure the following considerations are set forth in the Circular, in part:[2]

1. The public, in dealing with any lawyer, is entitled to rely upon the fact that he has never been convicted of a felony.

2. The honor of a great profession demands its members to be above reproach.

3. The fact that some lawyers, still in practice, may actually have committed acts that, if revealed, would result in their conviction as felons is no argument for setting up a procedure whereby those felons who have been cast out will again be put in position to wreak harm upon their clients.

4. A former lawyer who has been discharged from prison can still earn a living in thousands of ways, just like any other man who is discharged from prison.

5. When a man adopts the legal profession and takes his oath he knows what is the uniform penalty if he is ever untrue to that oath.

6. When a lawyer is being tempted, the knowledge that discovery will mean that he can no longer be a lawyer as long as he lives will operate as a stronger bar to aid him in overcoming the temptation than would the hope that he might be able to practice again despite the contemplated felony.

7. The public would gradually get the idea that many lawyers were former convicts. The entire profession would be cheapened and the honest lawyers would be harmed.

8. A profession that demands honesty and character in the highest degree also demands an inexorable rule that he who has been unfaithful shall go forth from the hall of justice and seek his living in an occupation where trust is not the indispensable condition of his activity.

9. Better far that some repentant convict be required to earn his living as do millions of his fellowmen than that a profession whose honor is a matter of public concern become sprinkled with men whose character has not met the test of life.

If for lawyer one reads physician, this sums up the argument against lowering professional standards, and against the bills *Senate Int. 60* and *Assembly Int. 67*.

Vocational Rehabilitation

On April 1, 1944, there was issued by the Office of Vocational Rehabilitation of the Federal Security Agency a *Manual of Policies*, a pamphlet of 27 pages setting forth the requirements and recommendations for physical restoration services for State Boards of Vocational Education and State Agencies for the Blind

This was followed on the same date by Supplement No 1, dealing with purchase of hospital care, and on June 15, by Supplement No 2, on suggested provisions for agreements with particular hospitals The whole program, both State and Federal, has not been as yet comprehended by most physicians, and comment thereon will be reserved by this JOURNAL until a later date

However, at a recent meeting of the subcommittee of the Public Health and Education Committee which is studying the whole subject of vocational rehabilitation with representatives of the New York State Department of Education and the State Health Department, the following informative data on the subject was elicited

In June, 1920 a federal law was passed providing for the rehabilitation of physically handicapped persons Anticipating this federal law, there was a law passed in New York State which became effective May 13, 1920 This became Article 47, entitled "Physically Handicapped Persons" The law of 1920, Section 1207, states "Application for rehabilitation —Any physically handicapped person residing within the state may apply to the Department of Education for advice and assistance regarding his rehabilitation (*L 1920, c 760* Eff May 13, 1920)"

Article 47 of the Education Law apparently has been amended from time to time Article 47-A entitled "Promotion of Vocational Education," was added by the Laws of 1932 It is understood that the federal laws were changed in July, 1943, which enabled the Federal government to pay moneys to states carrying on a program rehabilitating physically handicapped persons The State law was changed by the Legislature in 1944 The former Article 47 was completely amended Article 47 is now entitled "Vocational Rehabilitation of the Physically Handicapped" The short title is "The Vocational Rehabilitation Law" This is under the Laws of 1944, Chapter 778, effective April 13, 1944 Following are Sections 1210 and 1211 of that law

"Sec 1210 Acceptance of law of the United States —The State of New York, through its legislative authority

"1 Accepts the provisions of any law of the United States making appropriation to be apportioned among the states for vocational rehabilitation of disabled persons,

"2 Empowers and directs the Board of Regents of the university, hereby designated the New York State Board for Vocational Education, to cooperate with such agency as the federal government shall designate to carry out the purposes of such law,

"3 Appoints the state treasurer as custodian of all money given to the state by the United States under the authority of such law, and such money shall be paid out in the manner provided by such act for the purposes therein specified,

"4 Authorizes and directs the Board of Regents of the university as the State Board for Vocational Education and the Department of Social Welfare to formulate a plan of cooperation in accordance with this article

(*L 1944, c 778* Eff Apr 13, 1944)"

"Sec 1211 Appropriation —Any appropriation made to carry out the provisions of this chapter, in addition to any moneys allotted to the state for a similar purpose by the government of the United States may be used for the payment of salaries, travel, maintenance and operation, and other administrative expenses including the purchase of necessary office furniture, supplies, et cetera, tuition, fees, books, and other training supplies, maintenance and traveling expenses of persons undergoing vocational rehabilitation, occupational examinations and license fees, medical and psychological examinations, placement, equipment, surgical fees, hospitalization and therapeutic treatment

(*L 1944, c 778* Eff Apr 13, 1944)"

It was mentioned that federal funds are appropriated for this purpose and allotted to states according to population New York State receives about 10 per cent of the funds allotted The Federal government does not administer the program in the states but leaves the administration to the states The Federal government, of course, must approve their program, schedule of fees, and policies From the federal funds

received, approximately two-thirds of the cost of administration is met. It is thought that the cost of service to the patients will be about one-half from federal funds and one-half from state funds.

This is the background of the Vocational Rehabilitation to date. Further editorial comment will be made in a subsequent issue on the working and administration of these laws in the State of New York.

Current Editorial Comment

Penicillin*

An amount of penicillin sufficient for the treatment of infectious cases of syphilis has been released to the New York State Department of Health by the Civilian Penicillin Distribution Unit of the War Production Board, upon consideration of the reporting of the results of treatment to the National Research Council, as a part of its study of this agent. Because of this commitment, the administration of this therapy is restricted to the following hospitals and supervising agents: Meyer Memorial Hospital, in Buffalo, under Drs. Earl Osborn and I. Jay Brightman; the City, University, and Memorial Hospitals, in Syracuse, under Drs. E. C. Reifenstein, George Group, and Thomas A. Laurie; Albany Hospital, under Drs. L. W. Gorham and Rudolph Ruedemann; and the New York City Rapid Treatment Center, under Dr. Evan Thomas.

Patients must be referred for treatment in these hospitals through the nearest district state health officer, who will be able to provide for the cost of transportation, hospitalization, and the drug itself. Categories acceptable for treatment include the primary and secondary stages, as well as asymptomatic cases with histories indicating infection of less than one year in duration. Infants of less than one year of age with congenital infections may also be admitted. While cases without prior treatment are preferred, some will be accepted because of failure to maintain regular routine treatment when less than ten units of such therapy have been administered, counting one injection of an arsenical as two units and one injection of bismuth as one unit.

The dosage and period of treatment with penicillin vary in accordance with the degree of central nervous system involvement as evidenced by an examination of the cerebrospinal fluid. The least dosage of penicillin, 1.2 million units, is supplemented with 320 mg. of mapharsen, over a period of 7.5 days. The greatest dosage is 4.0 million units without accessory arsenical therapy, administered in 13.5 days. Infants are treated with a total dose approximately twice as great per pound of body weight as that prescribed for the adult.

Information now available from the short-term observation of penicillin-treated patients indicates that less than 0.6 million unit frequently fails to cure, while doses of 0.6 to 1.2 million units are attended by relapse rates which are in inverse proportion to the size of the dose. Since the attainment of a biologic cure becomes more difficult in the cases of longer duration, 2.4 million units are utilized routinely in the asymptomatic cases with histories of infection within one year, upon the assumption that most of these will have passed through their primary and secondary stages. Also upon the basis of this generalization, no cases of more than one year's duration are treated, for the allocation of penicillin is inadequate for the large doses which would be required. There seems to be no indication as yet that the asymptomatic patient whose infection is of unknown duration should be treated with this agent. Observation will be maintained for at least one year. It is expected that approximately six months will elapse in most seropositive patients in whom treatment has been successful before a negative serologic reaction is attained. It is to be anticipated that approximately 10 per cent of treated cases will require retreatment because of (1) the development of clinical evidence of relapse, such as darkfield positive lesions; (2) serologic relapse—the appearance of a strongly positive reaction in a patient who had attained seronegativity or a low titer; (3) serologic resistance—the persistence of a uniformly high titer over a period of more than six months; and (4) reinfection.

ANOMALIES OF THE SPEECH MECHANISM AND ASSOCIATED VOICE AND SPEECH DISORDERS

JAMES S GREENE, M D , New York City

(*Medical Director, National Hospital for Speech Disorders*)

LARYNGEAL involvements and oral anomalies are often of greater significance than we at first appreciate They are significant not only in themselves, but also because of their effects on the all important speech function and, in turn, on the total personality An abnormality which in another locus might be relatively unimportant, when present in the speech mechanism may cause a speech defect that seriously handicaps the individual in both his vocational and social adjustments

These anomalies, however, present several interesting contradictions Perhaps the most surprising is the comparative unimportance of anomalies of the tongue, in so far as they affect the speech function

From time immemorial the tongue has been considered the principal organ of speech It is recorded in the fourth chapter of Exodus that Moses complained "I am slow of speech and of a slow tongue" Isaiah prophesied that on the day of judgment "the tongue of the stammerer shall be ready to speak plainly" And St Mark wrote "The string of his tongue was loosed and he spake plain" Even the medical man has considered the tongue the organ of supreme importance in speech Galen, for instance, attributed stuttering to debility of the lingual muscles Celsus advocated rubbing the tongue with laserwort when the patient could not "articulate" And as late as the middle of the last century eminent European surgeons attempted to cure various speech defects by operating on the tongue But, despite the importance traditionally centered on that organ, the tongue may be completely extirpated without greatly interfering with the speech function

. *Case 1*—I have in mind the case of a man, 77 years old who developed a cancer of the tongue some sixteen years ago The surgeon prescribed radiation therapy which apparently arrested the condition for some time About two years ago, however, it became necessary for him to perform a glossectomy When we saw the patient a few months later, the tongue had been completely extirpated, nevertheless, his speech was surprisingly well articulated and distinct

Of the less serious tongue conditions the one of which we most often hear is tonguetie (ankyloglossia) But, despite the frequency with which the layman diagnoses as "tonguetie" any speech defect for which he cannot otherwise account, it is a comparatively rare condition In examining over 40,000 speech sufferers in our hospital, we have seen only ten or twelve cases of genuine tonguetie

In true ankyloglossia (Fig 1) the frenum is abnormally short and attached to the tip of the tongue, or so close to it that it seriously interferes with free movement and consequently with speech When an attempt is made to protrude the tongue, it arches in the middle of the dorsum

Another tongue condition which may interfere with speech is papilloma of the tongue The interference with articulation is usually slight, but the condition is interesting because it is so seldom seen Only one case has come under my personal observation, and that was the case of a boy of 7 (Fig 2) who had a papilloma in the midline of the dorsum of the tongue The growth was subsequently removed, and the child has had no further trouble

None of these tongue anomalies is seen as often as are abnormalities of other parts of the speech mechanism Clefts of the palate, for instance, are much more common and, in general, have much more serious effects on speech

According to recent statistics, approximately one child in every thousand is born with a cleft of the lip or palate or both This means that every year, in New York State alone, over two hundred babies are born with such deformities Almost without exception these palatal defects have a marked influence on speech and thus they present a special challenge to the surgeon a challenge not merely to repair the palate but to repair it in such a way as to insure its best possible functioning for the production of speech I emphasize this point because in cases in which the cleft is not extensive, the unmitated are often misled by its apparent insignificance into attempting operative procedures without having had any special training in this type of work Often the deformity following such surgical repair is worse than the original deformity, because the novice fails to consider the gross effects of cicatricial tissue contraction

Case 2—This was true in the case of Richard H Richard had a bilateral cleft of the lip associated with a unilateral cleft of the palate extending

Read at the Annual Meeting of the Medical Society of the State of New York New York City May 9 1944

FIG. 1. Ankyloglossia (front view) in a girl 8 years old.

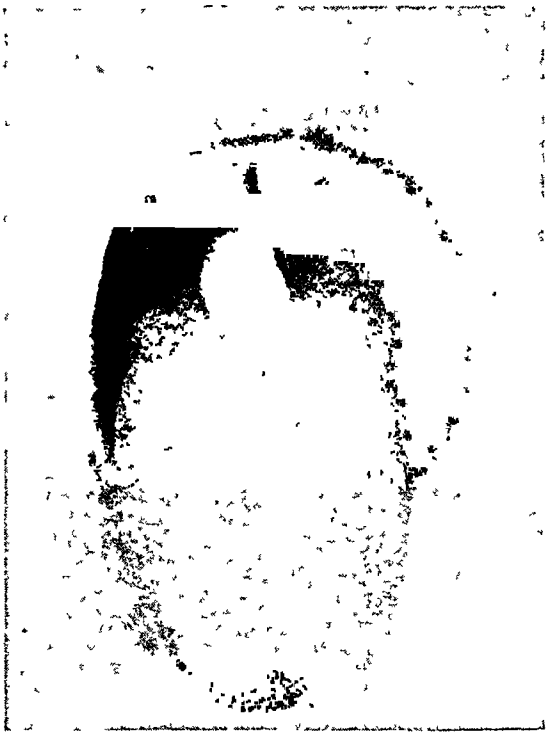

FIG. 2. Papilloma of the tongue.

FIG. 3. Marked oral and facial defects following repair of cleft lip and attempted repair of cleft palate.

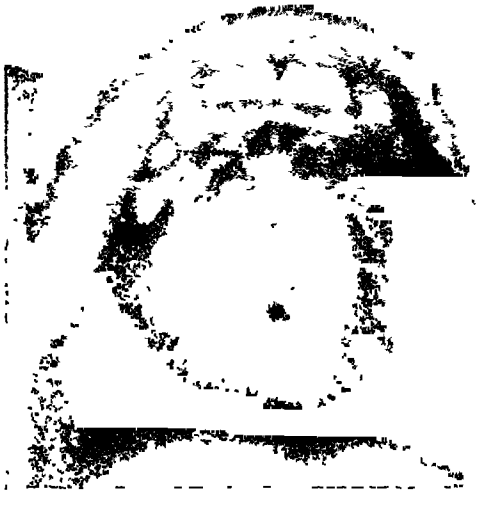

FIG. 4. Pinhole opening in palate of woman, age 34. Patient never received speech training, and her articulatory defect is pronounced.

through both the soft and hard palates and the alveolar process Three operations performed on his lip and palate before he was 2½ years old were all unsuccessful At 18, operative measures were again begun The palate was considered nonoperable, but the lip was operated on four times over a period of two years The operation left the patient with marked oral and facial defects, and scar tissue formation greatly reduced the size of his oral opening (Fig 3) When the patient was seen in our clinic, at the age of 21, the cleft in his palate still remained and a dentist had tried to block it with a hard rubber obturator The obturator did not fit well and allowed a leakage of air all around In brief, all the surgical and dental results were very poor, and the patient's speech defect was pronounced

The appliance with which this patient was fitted was of the so called plug type There seems to be a question as to which is better this plug type device, or the hinged-type artificial larynx (the velum movable extension appliance) There appears to be no standard technic for the making of either type and no general agreement as to what material to use There are appliances made of hard rubber soft rubber, gold alloys, steel alloys, and acrylic products such as luxene, vernonite and lucite I am sorry to say that, regardless of the type of appliance or the material used, most of those that I have seen do not fit properly

Before leaving the subject of cleft palates I should like to emphasize the importance of speech training for patients with this type of defect In almost every case, regardless of the success of operative measures, speech training is necessary This is because the operation is usually not performed until the child is at least 3 4 or 5 years old, and by that time he has already begun to talk and to develop many faulty speech habits Moreover, for each faulty speech pattern he has also built up a definite neuromuscular pattern that can be changed only with great difficulty The operation does not alter these patterns and for this reason the child usually continues to show very much the same type of speech defect as before Further, there is the important factor of scar tissue contraction, which tends to restrict function and pliability of the supporting tissues and, at the same time, to foreshorten the soft palate The foreshortening of the palate leaves an abnormally wide postnasal space which makes it difficult for the patient to control the escape of air into the nose and almost inevitably causes his speech to be characterized by an unpleasant nasal intonation

We feel that, if possible, speech training should be instituted even before the operation—in fact just as soon as the child begins to talk—in order that the correct neuromuscular patterns may be built up We have recently had occasion to see two cases which, in their contrasts, illustrate the value of early speech training

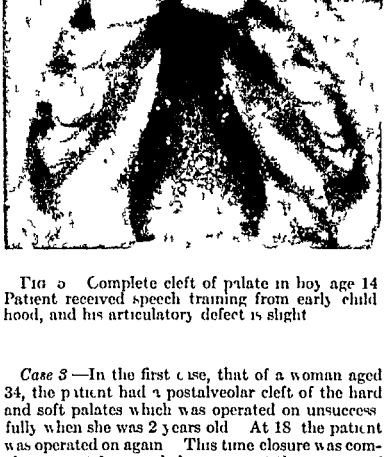

FIG 3 Complete cleft of palate in boy age 14 Patient received speech training from early childhood, and his articulatory defect is slight

Case 3—In the first case, that of a woman aged 34, the patient had a postalveolar cleft of the hard and soft palates which was operated on unsuccessfully when she was 2 years old At 18 the patient was operated on again This time closure was complete except for a pinhole opening at the junction of the hard and soft palates (Fig 4) However, since the patient had never received speech training, her speech is still nasal, indistinct, and almost completely unintelligible

Case 4—In the second case, that of a boy of 14 the patient had a bilateral complete cleft of the lip associated with a cleft of the hard and soft palates An operation on the lip was performed when he was 11 days old, it was followed by a second operation when he was 3 months old The palate has never been repaired (Fig 5) The reason is interesting The patient's mother knew an older child who had been operated on for a cleft of the palate but whose speech, in spite of the operation, was still very defective She felt that if the operation could do no more for her son there was no point in subjecting him to the ordeal Instead, she gave him speech training over a period of years and some time ago brought him to our clinic for further work In spite of his complete cleft, his speech is well articulated distinct and characterized by surprisingly little nasality

In conclusion, I want to touch briefly on the problem of rehabilitating the patient who has undergone a laryngectomy It has often been said that of the various types of malignant growths cancer of the larynx, when operated on in time offers the most favorable prognosis as far as saving the patient's life is concerned However, removal of the larynx poses a new and what seems to many patients anal most insurmountable problem After leading full and active lives for forty, fifty, or sixty years, they suddenly find themselves completely voiceless and, in con-

sequence, cut off from most avenues of employment and greatly handicapped in all their interpersonal relationships.

The surgeon who operates on these patients may follow one of three courses after the operation. He may consider his responsibility ended and dismiss the patient with no advice other than to return for an occasional "check-up," in which case the individual will, in all probability, remain voiceless for the rest of his life. On the other hand, he may recommend that the patient use an artificial larnyx, or he may refer the patient to a clinic for training to develop an esophageal voice.

If the surgeon recommends an artificial larynx, about the the only type the patient will be able to obtain at present is one operating on the reed principle, which is a modification of the mechanical larynx first devised by Czermak in 1859. It consists of a hollow metal cylinder containing a reed attached, on one end, to a small rubber tube which the patient holds in his mouth and, on the other end, to a larger tube which he inserts into his tracheal fistula. The current of air expired from the trachea sets the reed in vibration and produces sound, which in turn the patient converts into speech.

This reed-type instrument has several obvious disadvantages, the principal ones being that it is unhygienic and conspicuous. We have been trying for some time to develop an instrument on a different principle, the principle of Mr. Gilbert Wright's Sonovox. This instrument consists of a small capsule containing two battery-connected coils, over which a diaphragm is stretched. When the capsule is pressed against the neck, over the glottal region, electrical contact is established and the diaphragm vibrates. The vibration is communicated through the tissues of the neck to the static air in the hypopharynx, setting the air in vibration and producing sound which the patient transforms into speech. This instrument, when perfected, should prove much more satisfactory than the old reed-type artificial larynx, but we have been unable under present wartime conditions to develop it properly. The main objection to it now is that it produces a loud buzzing noise which drowns out the patient's speech.

However, any type of instrument is an encumbrance to the patient. Fortunately, it is usually possible for him to develop a substitute voice without the aid of such devices. At our postlaryngectomy clinic, we train these patients to phonate by using the esophagus in lieu of the larynx. The resulting esophageal voice is much more satisfactory than that produced by the artificial larynx, and enables the patient to carry on his normal, everyday activities, even to the extent of using the telephone.

Summary

Laryngeal involvements and oral anomalies, with a few exceptions, are important primarily because of their effects on voice and speech. An abnormality, which in itself is relatively unimportant, when present in the vocal or articulatory mechanism may cause a voice or speech defect that seriously handicaps the individual in all his interpersonal relationships. Contrary to popular opinion, however, abnormalities of the tongue, in general, have comparatively slight effects on speech; the tongue may be completely extirpated without greatly interfering with articulation. Clefts of the palate have much more serious effects on the speech function. Closure of such clefts, whether by operative repair or by mechanical appliances, does not in itself remedy the speech defect. Speech training is necessary and should be instituted as early as possible.

A different type of problem is presented by the patient who has undergone laryngectomy and has completely lost the normal voice-producing mechanism. Such a patient may be fitted with an artificial larynx, or he may be trained to develop a substitute voice by using anatomic structures other than the larynx. The artificial larynx has many disadvantages, but it is fortunately possible, in most cases, for the patient to develop a substitute voice without resorting to any mechanical device.

UNIVERSITY OF ILLINOIS ANNOUNCES SPRING REFRESHER COURSE IN OTOLARYNGOLOGY

The fifth semiannual refresher course in laryngology, rhinology, and otology will be conducted by the University of Illinois College of Medicine at the College in Chicago, March 26–31, inclusive, 1945. While the course will be largely didactic, some clinical instruction will be included. This course is intended primarily for ear, nose, and throat specialists.

As the registration is limited to thirty, applications will be considered in the order in which they are received. The fee is $50. When writing for application please give details concerning school and year of graduation, past training, and experience. Address applications to Dr. A. R. Hollender, Chairman, Refresher Course Committee, Department of Otolaryngology, University of Illinois, College of Medicine, 1853 West Polk Street, Chicago 12, Illinois.

HYPOPROTHROMBINEMIA: EFFECT OF ORAL AND PARENTERAL THERAPY WITH SYNTHETIC VITAMIN K SYNKAYVITE *

NORMAN H LETOURNEAU, M D , New York City

(From the Graduate Surgery Department, New York Medical College and Flower Fifth Avenue and Metropolitan Hospitals)

THE first synthetic vitamin K preparation, introduced by Almquist and Klose (2-methyl, 3 phytyl-1, 4-naphthoquinone), and those that followed had the disadvantages of low solubility and some toxic properties Therefore investigators instituted a search for products that did not have these unwanted characteristics This paper deals with one such preparation known as synkayvite, or 2-methyl 1 4-naphthohydroquinone diphosphoric acid ester tetrasodium salt It occurs as a white, crystalline powder which is exceedingly hygroscopic and very freely soluble in water

Effect of Synkayvite Therapy

The purpose of this study is to record the response of hypoprothrombinemic patients to oral and intramuscular synkayvite therapy and to determine, within a reasonable degree of accuracy, the time required for this response to take place

An attempt was made to select nonjaundiced patients for this series, as it was deemed advisable to use patients with minimal liver damage to determine accurately the response to synkayvite However, as liver damage in the three jaundiced cases listed in Table 1 was not great enough to interfere appreciably with the response to synkayvite therapy, they were included in the series

Recorded in Table 1 are the results of the study This table lists 20 patients whose prothrombin time ranges between 30 and 40 per cent of normal To 12 patients in this series 10 mg of synkayvite was administered intramuscularly and ten to twenty-four hours after injection the prothrombin time was determined If, after twenty-four hours, the prothrombin time had not returned to normal limits, 10 mg of synkayvite was again administered intramuscularly and the prothrombin time determination repeated in twenty-four hours This procedure was followed every twenty-four hours until a normal prothrombin time was obtained To 8 patients in this series 10 mg of synkayvite was administered orally and this dosage was likewise repeated every twenty four hours until a normal prothrombin time was obtained

* Vitamin K like compound synthesized by Hoffmann La Roche Inc Nutley New Jersey who provided generous supplies for this study

Determination of Prothrombin Time

Determination —A modification of the Quick method was used to determine the prothrombin times

The bactothromboplastin used by us is prepared from rabbit brains and standardized by the Difco Laboratories of Detroit It is put up in ampules containing 0 15 Gm of powdered rabbit brain In preparing the thromboplastin solution as it is used in performing the test, the contents of one ampule is deposited in a well-cleaned test tube and to this is added 2 5 cc of 0 85 per cent solution of sodium chloride and 0 05 cc of a tenth molar solution of sodium oxalate This mixture is then incubated in a water bath at 45 C for ten minutes, with frequent stirring After incubation the mixture is centrifuged slowly for three minutes, following which the milky thromboplastin solution is then separated from the particles at the bottom of the tube Four and one-half cc of blood is removed from the patient's arm by means of venipuncture and deposited in a test tube containing 0 5 cc of a tenth molar solution of sodium oxalate and thoroughly mixed The blood is then centrifuged at a slow rate of speed for five minutes and the plasma drawn off into a second test tube

We suggest that small test tubes be used in these determinations because of the small amount of reagents used and to allow a more accurate determination of the clotting point One tenth of a cubic centimeter of prepared thromboplastin solution is added to one tenth of a cc of patient's plasma and thoroughly mixed One tenth of a cc of fortieth molar calcium chloride is added and the time which elapses before clotting begins is measured by means of a stop watch Constant observation and maneuvering of the test tube is necessary to obtain an accurate clotting time Using standardized bactothromboplastin, normal clotting occurs in fifteen to sixteen seconds If the patient has hypoprothrombinemia the clotting time will be prolonged to more than sixteen seconds

Prothrombin Time Determinations

In the course of this study the prothrombin times of more than 120 patients at Flower-Fifth Avenue and Metropolitan Hospitals were determined The diagnoses in these cases cover a

TABLE 1.—Prothrombin Time Before and After Synkayvite Therapy

wide range, some of the most noteworthy of which are listed in Table 2.

Discussion

Although 20 cases are listed in Table 1 in which the prothrombin was as low as 30 per cent and not greater than 40 per cent of normal, no bleeding tendency was observed in any case that could be attributed to hypoprothrombinemia or that was checked by synkayvite therapy. It has been reported by investigators that bleeding does not occur until the prothrombin of the blood is reduced to markedly low levels; i.e., below 10 per cent of the normal in the human. This series would tend to substantiate the fact that there is a wide margin of safety in the prothrombin factor.

Table 1 shows a high incidence of hypoprothrombinemia in patients with carcinoma. The majority of patients with carcinoma reported in this study had advanced cases, and it would appear that there is a correlation between the stage of carcinoma and the degree of hypoprothrombinemia.

The incidence of hpyoprothrombinemia was also high in patients with pulmonary tuberculosis as shown in Table 2. Two cases reported in Table 1 (7 and 8) had hemoptysis. However, synkayvite therapy was followed by a normal prothrombin time and did not check the hemoptysis. It would appear that the hemoptysis in these patients was not related to the coexisting hypoprothrombinemia.

A patient with terminal uremia with marked liver damage was found to have prothrombinemia. It was interesting to note that this patient did not respond to synkayvite therapy. This was expected.

Oral synkayvite therapy caused a rapid rise in the prothrombin level in one case and in the remaining cases there was a gradual rise to normal in from forty-eight to seventy-two hours. This is explained by the fact that the effect of oral synkayvite depends on the amount absorbed from the gastro-intestinal tract. Oral administration of synkayvite, in the majority of cases, returned the prothrombin time to normal in forty-eight hours.

In all cases of hypoprothrombinemia in which liver function was unimpaired, synkayvite administered intramuscularly caused a rise in the prothrombin level to within normal limits in ten to twenty-four hours.

In one patient with obvious liver impairment, intramuscularly administered synkayvite did not cause a rise of the prothrombin level to normal until forty-eight hours had passed.

Conclusions

1 In nonjaundiced patients with unimpaired liver function when a prothrombin deficiency exists, the prothrombin level can be raised to within normal limits in ten to twenty-four hours by giving 10 mg of synkayvite intramuscularly

2 In patients with impaired liver function who have a prothrombin deficiency, the rate at which the prothrombin level can be raised after 10 mg of synkayvite is administered intramuscularly depends on the degree of liver impairment

3 The efficacy of orally administered synkayvite appears to depend on the amount of absorption that takes place in the gastro-intestinal tract

In patients with unimpaired liver function the prothrombin level can be returned to normal in from twenty four to seventy-two hours A normal level is usually attained in forty-eight hours

In patients with liver impairment the rate at which the prothrombin level can be raised depends on the degree of liver damage

---

"DOCTOR JONES' SAYS—

We were talking here recently about the shortage of doctors due to the war And of course along with that we're low on nurses and the hospitals are short handed The result is a lot of people if they have sickness in the home they re pretty much on their own But there s one thing that s helping out an awful lot in places where they re taking advantage of it and that's these Red Cross courses in home nursing

It reminds me of an old lady I used to be well acquainted with—lived over on the Long Brook Road She had to testify, in court on a case where sickness was involved and she made some reference to her nursing experience The lawyer asked her if she was a trained nurse and she said "Yes ' He asked her where she got her training 'I aking care of my mother," she says

Well that experience could ve been valuable but the trouble with her was she didn t know enough about it to recognize that she wasn't a nurse It s different with the folks that've had these Red Cross courses They learn a lot and one thing they learn is that they aren t nurses In other words they know their limitations Even a little knowledge if it's the right kind, is worth having It's when we don't recognize that it is only a little that it may be dangerous And a little, plus a little more—that's about all any of us've got

Anyw like twelve two hot experienced people hat take 'em (mothers, u ughters even pop, if he s interested) they learn to do a lot of things that'll help out the doctor and that'll always come in handy Taking temperatures, making up a bed with the patient in it giving baths fixing up a food tray so it'll look inviting keeping records of medicine and symptoms—those re just a few items that occur to me What they get—it's things that, war or peace, somebody in every home ought to be acquainted with

A doctor trying to look after a sick patient without any intelligent support—it makes me think of the colored woman I went to see years ago When I put the thermometer under her tongue she couldn't shut her lips So I said 'Allright, we ll put it under your arm " 'No suh " she says I ain' goin' to have that thing under mah arm!' 'Why not?' I said "'Cause a doctah put one there once an' *it didn't do me no good!*'—*Paul B Brooks, M D , in Health News, Nov 21, 1944*

TUBERCULOSIS AS AN INDEX OF SOCIAL PROGRESS

It is often said that the death rate from tuberculosis is a delicate index of social progress If this is so one of the most striking features in the history of public health is the steady decline of both pulmonary and nonpulmonary tuberculosis during the past two generations There are many factors responsible for this decline including a higher standard of living better housing, and better education but these are only contributory It must never be forgotten that tuberculosis is first and last an infectious disease Anything that increases the risk of infection will cause a rise in the incidence of the disease, and anything that diminishes that risk will result in a rapid improvement in the figures—*James Mackintosh, M D, New Jersey Pub Health News Dec, 1943*

PENICILLIN—THE RAPIDITY OF ITS EFFECT IN THE TREATMENT OF GONORRHEA

VERNON M. DUNFIELD, Capt., (MC), AUS, and ADRIAN MANDEL, Lt., (SC), AUS

IN MAY, 1943 Herrell, Cook, and Thompson[1] reported the results of the use of penicillin in the treatment of three cases of gonorrhea. Since that time many articles have appeared, notably those of Keefer *et al.*,[2] Mahoney *et al.*,[3] Ferguson and Buckholtz,[4] and Turner and Sternberg,[5] which have shown penicillin to be a very effective and rapidly acting agent in the treatment of gonorrhea. The following study was undertaken to determine, if possible, the rapidity with which penicillin would bring about a clinical and laboratory cure of gonorrhea. Miller and associates[6] have since published some results of studies in this regard.

Methods

The study is based on 154 nonselected male patients as they presented themselves for treatment. The only requirement for inclusion in the series was the presence of a urethral discharge, positive for gonorrhea by smear or culture, and resistant to at least five days of sulfathiazole therapy. The dosage used in all cases was 100,000 units given in 20,000-unit doses at intervals of three hours by the intramuscular route.[7] Though all cases were proved to be gonorrheal in origin, it was not possible to secure positive smears in every instance on the day on which therapy was instituted. A urethral smear was made on each case on the morning on which therapy was initiated and every three hours thereafter prior to each injection until completion of therapy. After each smear was made, the patient was instructed to urinate and not to empty the bladder again until the next smear was obtained. Records were kept of these smears and correlated with the amount of urethral exudate, which was arbitrarily represented as one, two, three, or four +. Urethral smears and cultures were secured on all cases at the end of twenty-four hours whenever obtainable. Cultures were made on chocolate agar plates and incubated in an atmosphere of 10 per cent carbon dioxide. The patients were seen daily for three days following treatment and then once weekly until three weeks had elapsed, except those cases presenting unusual features, when the patients were hospitalized longer and followed more closely. In those cases responding promptly to penicillin, no tests of cure were used other than clinical observation. In this connection the writers wish to call attention to an article by Turner and Sternberg[5] on "The Management of the Venereal Diseases in the Army" and also to the teaching of Pelouze[8] on indiscriminate manipulations of the urethra infected with gonorrhea.

Discussion

Of 154 cases, positive smears were demonstrated in 117 at the outset of treatment. Of the remaining 37 cases, 11 exhibited either positive smears or extracellular organisms later on in the series of three-hour smears. Six cases showed extracellular organisms at the outset, and 20 remained negative throughout. These findings are represented in Table 1, where the results are further analyzed. The important fact here seems to be that, after receiving varying amounts of penicillin, 7 cases changed from negative to positive; 4 cases with negative smears at the outset later showed extracellular organisms, and three cases with extracellular organisms at the outset later became positive. These 37 cases, with two exceptions (see Table 2), showed complete recovery, including the 20 cases that were negative throughout. It would appear from these data that any patient with a proved case of gonorrhea and a persistent urethral discharge following treatment with sulfonamide should have the benefit of penicillin therapy even though a positive smear or culture is not obtained.

Table 3 is a representation of the results of urethral smears made at three-hour intervals. The first line of the table presents the results on the total 154 cases, with the percentage negative given in parentheses. The second line of the table gives the results only on those cases which were positive at the beginning. Fourteen instances were noted in which a discharge became negative to smear examination and later reverted to positive. This reversion occurred at varying times between six and twelve hours from the beginning of treatment, i.e., when between

* Patients previously treated with one course of penicillin at other installations

40,000 and 80,000 units of penicillin had been administered. No correlation could be drawn between the time and dosage factor and the reversion to the positive state. When the study was undertaken it was hoped to draw some conclusions from the result of serial smears as to the time in which penicillin would bring about a clinical and laboratory cure of gonorrhea. It was early apparent that this was not possible for the following reasons: (1) As outlined above, smears which became negative did not indicate a permanent cure. (2) In order to demonstrate the time of cure, the treatment would have to be terminated at various intervals in the schedule and followed for evidence of recurrence or persistence in groups of significant size. It is to be noted, however, that the largest number of smears to become negative did so in the first three hours, and the second largest group did so in the second three-hour period, in which the patients had received a total of 20,000 units and 40,000 units, respectively.

In Table 4 are shown the follow-up results in the three cases of the series which were still bacteriologically positive after twenty-four hours. Case 2, who showed the most persistent discharge, was given the second course of penicillin three days following the initial therapy. This was deemed necessary because this patient presented a profuse yellow, purulent, urethral discharge in contrast to the grayish, thin, mucoid exudate frequently noted for several days in cases responding to therapy.

From the foregoing it appears that there were no treatment failures in the series, but this is not the case. In Table 2 are set forth the cases which were negative to both smear and culture on the twenty-four hour examination that were treated with more than one course of penicillin because of persistent discharge which became positive bacteriologically at some time during the twenty-one-day follow-up period. One of these cases went on to recovery, the remaining six were treatment failures and were referred to General Hospital for further treatment. These represent a failure rate of 5.2 per cent for the entire series. Failure of therapy was judged by the persistence of a thin mucoid discharge following three courses of penicillin. These discharges were negative to cultural examination in all instances, but in some cases continued to show, at intervals, extracellular gram-negative diplococci. In Table 5 are shown the results of the serial smears in each of these six resistant cases, together with the number of days following each treatment that positive smears were obtained. The patients were lost to observation at periods varying from four weeks to four months, but in all instances they continued to show an intractable exudate. The fact that seven cases were negative to smear and cultural examination at the termination of the first twenty-four hours and later reverted to a positive status is indicative that a careful follow-up program is as essential after penicillin as after any other drug. Cases 2, 3, and 6 received, on their third course of penicillin, an initial dose of 100,000 units followed by 20,000 units every three hours for five additional doses. It is felt that persistence of the discharge in these cases, at least, is due not to insufficient dosage but rather to certain anatomic conditions, the details of which are worthy of mention, in that in each case mechanical abnormalities or other well-recognized reasons for treatment failure were present.

Case Reports

Case 1.—A stricture of the pendulous urethra was present, about midway on the penile shaft, which admitted a number 11 Fr. sound with difficulty.

Case 2.—History of a penile discharge for the seven months preceding the initiation of penicillin therapy was given. Previous treatment had consisted of numerous courses of sulfathiazole at other installations and one course of fever therapy. The prostate was large and boggy and its secretion contained many leukocytes. This is a case of chronic gonorrhea with prostatic involvement.

Case 3.—A history of gonorrhea four years pre-

TABLE 3.—Serial Smears Taken at Three-Hour Intervals Throughout Treatment Course

* 3 cases include one which started treatment with a negative smear.

viously, followed by an intermittent penile discharge, was given. This persisted in spite of extremely large quantities of sulfonamides, urethral instillations, and prostatic massage before and after he came under our observation. The sudden onset of profuse gonorrheal discharge and history of a recent exposure after he had been under treatment for nonspecific prostatitis classifies this case as a reinfection complicating a chronic prostatitis which was originally gonorrheal in origin.

Case 5.—The patient had a history of at least eight attacks of gonorrhea. Penicillin was given at another hospital two and a half months before, but discharge was said to have persisted ever since as a morning drop. Reinfection was denied, but the patient presented a profuse purulent discharge indicative of a reinfection.

Case 6.—There is a history of an intermittent discharge for thirteen months, during which nine courses of sulfathiazole and one course of heat therapy were administered. A positive smear was obtained after urethral sounding for a stricture of the bulbous urethra.

Case 7.—There was a history of recurrent urethral discharge ever since he had been treated with penicillin six weeks previously at another hospital. First degree hypospadias was present.

Summary

One hundred fifty-four nonselected cases of proved gonorrhea were studied from the standpoint of determining the rapidity of the action of penicillin in gonorrheal urethritis. There is a rapid disappearance of the gonococci from the urethral exudate, as indicated by urethral smears. We are unable, however, to duplicate the uniformly successful results of Miller and his coworkers,[6] in that we were able to demonstrate only 50.4 per cent negative in three hours and 84.6 per cent in six hours from 117 cases that were definitely positive at the start of therapy. The greatest increment of change from positive to negative occurs in the first six hours, but it is apparent that this change is not necessarily a permanent one and that reversions to positive occurred in an appreciable number of cases. In uncomplicated cases the results of treatment were uniformly successful though retreatment was necessary in two cases. Subjective symptoms disappear very rapidly, usually in the first three to six hours, and the amount of discharge decreases in a manner remarkably parallel to the disappearance of the gonococci from the smears. The character of the discharge rapidly changes from that of a profuse yellow pus to a thin, grayish mucoid exudate, which persists on an average for three days in cases responding to treatment. Failure of other observers to note this is possibly due to neglect in instructing patients to avoid urination until examined. Treatment failures are obvious very early and the best guide here is the clinical appearance of the exudate, which persists or recurs as a whitish-to-yellow, somewhat thicker exudate that may or may not show the presence of intra- or extracellular gram-negative diplococci. Care should be exercised in post-treatment follow-up, since it is evident that recurrences do occur. In the presence of factors which interfere with drainage, penicillin treatment was found not to be uniformly successful.

TABLE 4.—Results in the Three Positive Cases at the End of Twenty-Four Hours' Treatment

1	6	4	1
2	14	3	2
3	11	3	1

Conclusions

1. In acute uncomplicated gonorrheal urethritis penicillin is an effective and rapidly acting drug. In 148 cases of this type so treated all but two patients recovered on one course of therapy, and these two responded to a second course. This is not to state that penicillin was effective in 100 per cent of cases, since the over-all rate for the series of 154 cases was 96.1 per cent recovery, over at least a three-week observation period.

2. Conditions which have always been an obstacle to successful treatment, such as prostatic involvement, stricture of the urethra, congenital

anomalies, etc., will continue to call for a careful search for their presence and rectification, if possible, according to well established urologic principles

3 With the exception of six cases in the total of 154 in the series, the clinical course showed a remarkable parallel to the results of the serial smears This is based on the disappearance of the subjective symptoms, and the amount of character of the urethral exudate

4 Delay in the disappearance of the gonococcus from the secretions of the genital tract occurred with sufficient frequency to warrant a cautious attitude in instructing patients on post-treatment conduct And it is to be remembered that although this is an effective therapeutic agent, the criteria of cure of gonorrhea are still as unsatisfactory as ever and the employment of tests of cure are of questionable wisdom

5 One of us (A M) made the observation that the appearance of the leukocytes under penicillin treatment differs greatly from that of those under sulfathiazole With penicillin therapy, the cell membrane, cytoplasmic granules, and nucleus were clearly defined and evenly stained, whereas under sulfathiazole these structures were typically hazy in outline and poorly defined

6 It is felt that it is impossible to make a statement as to the time in which penicillin would bring about a complete and permanent cure, since reversions to positive status were noted both during the course of treatment and also during the follow-up period

TUBERCULOSIS INCREASE IN ENGLAND A WARNING TO HEALTH WORKERS

Present experience in England presents a warning to public and industrial health workers that must not be overlooked This is the present sharp increase in tuberculosis, which has been especially large among women in general and particularly among young women The cause for this increase in the tuberculosis death rate is the most difficult health problem confronting the health authorities in England It is felt that overcrowding, poor nutrition, worry, and many other factors are all contributory, but as yet the one chief factor has defied recognition, as well as the reason for the predominance among young women —*H Kronenberg M D, in J A M A, Mar 11, 1944*

MULTIPLE SCLEROSIS COMPLICATING PREGNANCY

C. H. PECKHAM, M.D., Cooperstown, New York.

(From the department of obstetrics, the Mary Imogene Bassett Hospital)

AMONG the unspectacular but nevertheless important advances in obstetrics during the present century has been a general increase in knowledge concerning the counterplay between acute and chronic medical disease on one hand and pregnancy, labor, and the puerperium on the other. Such conditions as rheumatic heart disease, tuberculosis, chronic vascular disease, and diabetes afford examples of conditions in which much painstaking work has been done and many articles have been published by both the internist and the obstetrician. Neurologic affections, however, seem to have commanded less attention in this regard, and authoritative references, at least in the American literature, are difficult to find. Particularly is this true of disseminated or multiple sclerosis, a condition ranking high in frequency in any list of nervous-system disorders.

It is not within the province of this essay to discuss in detail multiple sclerosis from a medical standpoint. A brief summary of the condition does, however, seem pertinent to pave the way for further observations. Multiple sclerosis is defined by Christian in the last edition of Osler's *Textbook of Medicine* as "a chronic affection of the brain and cord, characterized by localized areas in which the nerve elements are more or less replaced by neuroglia. This may occur in the brain or cord alone, more commonly in both." The condition most commonly manifests itself in persons between the ages of 20 and 40 and apparently occurs more commonly in men than in women, the ratio being approximately three to two. The cause is obscure. Trauma, fatigue, cold, exposure, intoxications, and infections have all been mentioned. In view of comments by European observers, it is interesting that the Association for Research in Nervous and Mental Diseases in its monograph, *Multiple Sclerosis*, does not include pregnancy as a predisposing factor. Pathologic changes are observed as areas of sclerosis in various portions of the brain and/or cord. In recently invaded areas there is an infiltration with mononuclear cells around the blood vessels with edema. Many authorities believe that the primary change is in the blood vessels—an obstructive thrombotic vascular lesion. Others consider it primarily an inflammatory lesion.

The symptoms and physical signs vary greatly with the individual case. Following early manifestations of the disease there may be marked remissions or even apparently complete recovery. As the disease progresses the sclerosis becomes permanent with signs and symptoms constant. Some workers consider that there are two types of multiple sclerosis: the commonest characterized by remissions and exacerbations, and the other a steadily progressive disease. Motor signs include weakness of the legs and stiffness, usually progressing to a spastic paraplegia, increase of deep reflexes, and loss of abdominal and cremasteric reflexes. Sensation is ordinarily not affected until late in the disease. Slurring speech, nystagmus, diplopia, partial or temporary complete amaurosis, an intention tremor, defective memory, emotional disturbances, and lack of control are commonly observed. In the later stages the patient is usually helpless because of paralysis of the legs. Death may be the result of the disease itself or frequently is due to some intercurrent infection. The average duration of the condition is twelve years, although many patients live much longer.

Evidence that multiple sclerosis may be congenital is subject to considerable scepticism. That a hereditary factor may occasionally be adduced is also a matter of debate, but here the evidence seems more convincing. Further study on this topic is in order and is a matter of interest to the obstetrician from a eugenic standpoint.

Since more than 40 per cent of the recognized cases of multiple sclerosis occur in women and since its incidence is highest in persons between the ages of 20 to 40 (the child bearing period) it seems reasonable to suppose that the condition would be observed not too rarely with pregnancy as a complicating factor. A survey of the English literature during the past twenty years reveals only two articles, one of these a case report, dealing with this subject. Moreover, multiple sclerosis is mentioned as a complicating factor of pregnancy in only two of the currently popular obstetric textbooks. On the other hand, European publications are replete with such articles, many of them including analyses of large series of cases but all of them, unfortunately, containing only scant information in many obstetric particulars.

Although previously several writers had reported one or more cases of multiple sclerosis

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 9, 1944.

complicating pregnancy, the first comprehensive survey of the subject was published by von Hosslin in 1904.[1] It was his opinion that the condition throughout pregnancy underwent distinct exacerbation. Following a study of the literature, he reported 2 cases of his own and 21 seen by other German observers. Among the latter was I. Hoffman, whose patient showed considerable exacerbation during pregnancy with a marked remission during the puerperium. On the other hand, Balint followed 2 cases through uneventful pregnancies, each exhibiting severe exacerbation after delivery. Irma Klausner had observed 11 cases and was of the opinion that multiple sclerosis tended to first manifest itself after too closely spaced child bearing, after operative delivery, or after postpartum hemorrhage. If the disease was already present it became more severe throughout the entire gestational process. Stenger saw 2 cases begin ning several weeks after a normal delivery and puerperium. Hoffman reported 5 cases, one of which manifested itself after the first delivery, remained stationary during two more pregnancies, but became worse after the third delivery.

The next comprehensive report was published by Richard Beck[2] in 1913. This author also quotes the experience of several other observers whose opinions diverged considerably. Thus Meyer-Rügg stated that there was no proof that any disease of the spinal cord was unfavorably influenced by pregnancy. Windscheid also felt that spinal conditions were no more likely to occur during pregnancy than at any other time. Edinger believed that although pregnancy itself had no effect, labor with its attendant overexertion might be a causative factor. E. Muller was of the opinion that a patient predisposed to multiple sclerosis but having never shown symptoms of it might manifest the condition during gestation, which provides "many moments of biological crisis." Offergeld claimed that pregnancy itself was not a cause of the disease but that changes occurring during pregnancy might act as an exogenous factor to favor the manifestation of symptoms. Furthermore, the irritability and instability of the nervous system at this time might further act as a predisposing factor. The author himself reported a series of 118 patients with multiple sclerosis, 40 of whom had borne babies. Of the 40, 16, or 40 per cent, showed evidence of a connection between the onset or course of the disease and pregnancy. It was his conclusion that if the disease manifests itself or becomes worse during pregnancy one must consider the advisability of therapeutic abortion or sterilization. Table 1 indicates Beck's experience in the sixteen cases above mentioned. This table shows that in eleven instances the onset of the disease was during gestation or in the early puerperium. Five cases had been diagnosed as multiple sclerosis prior to conception and all of these showed exacerbations during or immediately after pregnancy.

Alpers and Palmer,[3] in an article published in 1929, state that myelitis is one of the most interesting neurologic complications of pregnancy. It may occur during pregnancy, immediately postpartum, or during the puerperium. Many of these cases, in von Hosslin's[4] estimation, are later found to be instances of multiple sclerosis, and with this view Oppenheim agrees. Von Hösslin even states that many cases which begin with peroneal palsy during pregnancy eventually develop into typical examples of multiple sclerosis.

Dimitz,[5] in 1928, quotes an analysis of 445 cases of multiple sclerosis collected from the literature by Kortum.[6] The latter found that 22 of these cases (5 per cent) began during pregnancy, while 32 (7 per cent) manifested themselves immediately after delivery. In addition there were 14 cases (3 per cent) that became much worse during gestation and 23 (5 per cent) showed exacerbations in the puerperium when the disease had been diagnosed prior to conception. Thus, in 445 cases including both sexes and all ages, pregnancy had an adverse effect in approximately 20 per cent. Careful analysis, however, revealed an unstated number of women with multiple sclerosis in whom pregnancy seemed to play no important role.

In 1934, thirty years after his previous work, von Hosslin[7] published a monograph on multi-

ple sclerosis. This contains an exhaustive compilation of the literature together with opinions expressed in personal communications to the author from many authorities. These opinions and conclusions do not add greatly to those already noted. The author now believed that "the influence which pregnancy, labor, and the puerperium has on inciting or exacerbating the disease is well known." Included in the monograph is an analysis of 516 cases and in 135 of these von Hosslin felt that he could accurately select the cause or predisposing factor. Table 2 indicates these supposed causes and shows that in 17 per cent of the total number pregnancy and labor were considered the deciding factor.

The last analysis from the literature to be mentioned at this time was published by Fleck in 1938. This article concerns itself with an expression of opinion on the part of German authorities as to the course to be advised in women of the childbearing age as related to the permission or interdiction for marriage or pregnancy, therapeutic abortion, and sterilization. The consensus of opinion was that marriage should not be prohibited but that pregnancy was generally unwelcome. It was the feeling of some that if a pregnancy was present in a woman with multiple sclerosis abortion and sterilization were uniformly indicated because of probable ill effect to the patient, because of possible transmission to the infant, and because of the fact that the disease made for an unsatisfactory mother. Others took a more conservative view and H. Eymess stated that multiple sclerosis is not an indication for interruption of pregnancy when the condition has improved in the past six months but only when definite progress of the disease has occurred during pregnancy. It was von Hösslin's final conclusion that abortion is indicated only if multiple sclerosis develops or becomes worse during a pregnancy. Even then sterilization is not to be insisted upon if the mother wishes at a later date to attempt another child.

Thus far the discussion has been limited to the effect of pregnancy on the disease. The question now arises, "What effect, if any, does multiple sclerosis have on pregnancy, labor, and the puerperium?" If one omits the very questionable congenital or hereditary transmission, the literature is singularly silent on this subject. Apparently the pregnancy progresses to term, normal labor supervenes, a living child is born, and the puerperium presents no undue obstetric complications. In the presence of any chronic disease the incidence of abortion and premature labor would be expected to be somewhat higher than in normal individuals. Furthermore, such patients might well exhibit puerperal or intercurrent infection somewhat more frequently. An item of considerable obstetric interest is manifested in two patients exhibiting both multiple sclerosis and pregnancy who were observed during recent years at the Mary Imogene Bassett Hospital. A brief résumé of these two cases follows.

Case Reports

Case 1.—E. H. This patient, a 26-year-old white woman, was first observed in the hospital in July, 1930. Her chief complaint was of difficulty in walking for a period of three months. This was associated with numbness and tingling in the legs. Other symptoms had been slight blurring of vision, intermittent headaches, partial incontinence, and urgency of urination. Physical examination revealed nystagmus, bitemporal pallor, absent abdominal reflexes, hyperactive deep reflexes, diminution of pain and touch sensation below the umbilicus, loss of vibratory sense in the lower extremities, marked ataxia, and spasticity of the lower extremities, more marked on the left. Laboratory findings were essentially negative, the spinal fluid was under normal pressure, and showed no increase in cells. Serologic tests for syphilis on both the blood and spinal fluid were negative. After her discharge from the hospital she was followed routinely in the outpatient department, the condition showing steady progression. The last menstrual period began on August 15, 1930. Throughout pregnancy the advance of the disease was, if anything, more rapid. Being near term and living at a considerable distance from the hospital, she was again admitted on May 12, 1931. On May 15, 1931, fairly strong and rhythmic uterine contractions could be palpated, and these continued. The cervix slowly dilated. Castor oil and quinine failed to increase the strength, frequency, or duration of these contractions, which felt to the palpating hand like those of normal labor. At no time was the patient aware of the contractions nor did she experience the slightest pain. On May 18 the patient finally delivered spontaneously a normal infant weighing 7 pounds 2, ounces. No anesthetic was necessary. Pituitrin administered postpartum caused strong contraction of the uterus. Following delivery there was little if any change in her condition for a year, but after this a spontaneous remission occurred. In August, 1934, she was rather remarkably better than when last seen. At this time she was two months pregnant and after due

consideration therapeutic abortion was performed. This procedure was done under gas-oxygen-ether anesthesia, so that perception of pain was not again tested. The patient was not again seen until 1938, when she was again pregnant. The remission previously noted had apparently endured for the intervening four years. At this time therapeutic abortion followed by tubal sterilization was performed. Following the latter procedure there was a marked febrile episode associated with a Staphylococcus aureus bacteriemia, the patient making so slow a recovery that she was not discharged for three months. Despite all this, however, there was no evidence of an exacerbation of the multiple sclerosis and when she was last seen (1940) her condition was less incapacitating than at the end of her term pregnancy nine years before. Sufficient signs and symptoms were still present so that it was felt that the initial diagnosis of multiple sclerosis had been correct.

This case seems of interest from several points of view, namely:

1. Steady progression of a previously existing multiple sclerosis throughout pregnancy.

2. A slow but completely painless labor ending in spontaneous delivery. No effect was observed on uterine contractions from the administration of castor oil and quinine. There was prolonged contraction of the uterus after delivery and following the administration of pituitrin

3. A remission occurred after a year after delivery and endured through two therapeutic abortions, tubal sterilization, and a marked febrile episode associated with Staph. aureus bacteriemia.

Case 2.—The patient, a 26-year-old primigravida, was first seen in the hospital in May, 1943. The first symptom, that of dull and persistent occipital headache, had manifested itself in November, 1939. Two months later she was admitted to another hospital because of numbness of the left side of the tongue and lip, difficulty in opening her mouth, and difficulty in swallowing. On examination loss of sensation along the fifth nerve distribution on the left was found. One month later blurred vision and difficulty in walking were noted. Re-examination showed amblyopia, anesthesia of the head and face, and a loss of taste sensation over the anterior two-thirds of the tongue. The deep reflexes were hyperactive and the abdominal reflexes were lacking. These signs and symptoms cleared remarkably, but a third episode associated with blurred vision, diminution in hearing, and blurred speech occurred in August, 1942. The last menstrual period occurred October 15, 1942. When seen in the hospital, the patient was in excellent general condition, the chief find
reflexia and absen
nancy progressed
delivered spontane
weighing 6 pounds, 5 ounces. The labor was stated to be six hours and consisted of relatively mild cramps in the lower back. No typical labor pains were observed throughout parturition. There was a slight and temporary recrudescence of symptoms in the early puerperium but when last seen (December, 1943) the condition showed no aggravation.

Discussion

Since the cause of multiple sclerosis is as yet unknown, it is impossible to offer positive statements as to the actual effect of pregnancy on the disease. Clinical experience, however, would seem to indicate the following as a rational course to pursue with the individual patient until more definite information is available. The disease is a chronic one and incapacitating, almost always progressing to a fatal termination. For this reason it seems logical to discourage matrimony once the diagnosis is made and confirmed. Multiple sclerosis manifests itself for the first time during pregnancy or shortly after labor too frequently to make it a mere matter of coincidence. It is, however, impossible to state whether gestation acts in some unknown way as a causative factor or a predisposing cause. Possibly alterations in the central nervous system normally occurring during pregnancy may play a role. Possibly the spasm of the smaller arterioles such as is observed in toxemia of pregnancy might initiate a train of events culminating in sclerosis of certain vessels in the brain and cord. Against this idea there has been presented no evidence that multiple sclerosis more commonly follows a toxemic pregnancy. Generally speaking, it is difficult for the obstetrician to consider a normal pregnancy, labor, or puerperium to be a period of particular stress or crisis to the individual. On the other hand, complications do occur which render the process a shocking one to the patient. It is believed by some that in all cases the multiple sclerosis has antedated the pregnancy but in a form so subliminal that symptoms have not occurred and diagnosis has been impossible until the added mysterious influence of pregnancy has accelerated the condition to a point where it becomes obvious. Whatever the cause, the pregnancy factor is in most cases evident and for this reason alone the married woman with multiple sclerosis should be warned against pregnancy. As an additional basis for this advice, there should be noted the fact that any crippling disease such as this, and particularly one in which emotional and mental disturbances are observed, renders the individual a most unsatisfactory mother.

If the patient is already pregnant when seen for the first time, the problem becomes somewhat different. A reliable history of several members of the family having had the disease will rarely be obtained and hence will usually play no role in a decision as to the advisability of therapeutic abortion. Furthermore, a fair number of cases have been observed in which pregnancy did not

seem to alter at all the course of the disease. Indeed, in any condition characterized by marked exacerbations and remissions, it will often be difficult to state definitely that the pregnancy was the actual cause of a period of increased intensity. Moreover, therapeutic abortion itself may cause mental and physical shock to the patient. Routine therapy is rarely a wise medical policy and the patient's welfare is usually best served by individualization. The pregnant woman with multiple sclerosis should be carefully studied. If the condition is far advanced or is progressing more rapidly since the onset of gestation, abortion should be advised. If the disease is in its early stages and shows no evidence of exacerbation, the pregnancy may be allowed to continue. The patient should be observed at frequent intervals by both the neurologist and the obstetrician. If other obstetric or accidental complications develop, making the situation more hazardous to the patient, termination of the pregnancy will probably be indicated. The labor should be conducted in the most conservative manner; the patient should be spared the strain of the second stage so far as possible; excessive postpartum blood loss should be scrupulously guarded against; and prolonged rest throughout the puerperium should be insisted upon. It will probably be better if the patient does not attempt to nurse her baby. In most cases sterilization in the puerperium by whatever means seem most conservative is to be advocated.

In conclusion, a plea should be made for the publication of reports of cases of multiple sclerosis complicating pregnancy. The combination is sufficiently rare so that only in this way may we increase our knowledge of the counterplay between the two conditions.

ADDITIONAL MEDICAL OFFICERS AND NURSES TO BE APPOINTED IN PUBLIC HEALTH SERVICE

Thomas Parran, Surgeon General of the Public Health Service, Federal Security Agency, announced on January 9 the date of examinations for appointment of additional medical officers and nurses in the commissioned Regular Corps of the Public Health Service. Interviews began February 5.

Written examinations are scheduled for April 23, 24, and 25.

Medical officers will be appointed in the grades of assistant surgeon and senior assistant surgeon, corresponding with the grades of first lieutenant and captain in the Army. Applicants must be citizens of the United States, graduates of recognized medical schools, and must be serving, or have served, a year's internship. Senior assistant surgeons must have four more years of professional training or experience.

Nurses will be appointed in the grades of junior assistant nurse officer, assistant nurse officer, and senior assistant nurse officer, corresponding with the grades of second lieutenant, first lieutenant, and captain in the Army.

The schedule of the Board of Examiners to meet applicants in Marine Hospitals is as follows: Boston (Brighton), February 5, 6; New York (Stapleton, Staten Island), February 7–10; Baltimore, February 14, 15; Norfolk, February 16, 17; Savannah, February 21, 22; Cleveland, February 26, 27; Detroit, February 28; Chicago, March 1–3; Kirkwood, Missouri (near St. Louis), March 12–14; Louisville, March 15; Memphis, March 17; Galveston, March 21, 22; New Orleans, March 23, 24; Mobile, March 26; San Francisco, April 5–7; Seattle, April 10–12.

Interviews also will be conducted in the U.S. Public Health Service Dispensary, Washington, D.C., February 12, 13, March 5, 28, and April 18; the Office of Indian Affairs, Minneapolis, April 16; the Public Health Service Hospitals, Fort Worth, March 19, 20, and Lexington, Kentucky, March 16; the Office of Malaria Control in War Areas, Atlanta, February 23; and the Public Health Service Relief Station, 406 Federal Building, Los Angeles, April 3, 4.

Application blanks may be obtained by writing to the Surgeon General, U.S. Public Health Service, Washington 14, D.C., or at the time the applicant appears before the Board of Examiners.

DIFFERENTIAL DIAGNOSIS OF EARLY LESIONS OF VENEREAL DISEASES

Borris A Kornblith, M D , F A C S , New York City

THE object of this communication is to set down the present minimal diagnostic criteria for the differential diagnosis of early acute lesions of the more common venereal diseases Stokes, in 1936, stated, The past fifteen years in clinical syphilology have provided the basis for as complete a reversal of diagnostic methods as applied to early syphilis as can be found in the field of medicine The diagnosis of early syphilis is no longer a clinical but a laboratory problem The collapse of clinical criteria has been brought about by the darkfield examination of genital lesions and by the blood Wassermann reaction "[1] What Stokes said about syphilis, as applying in 1921, may be restated now in 1945 with equal emphasis on behalf of the so-called minor venereal diseases —i e , chancroid, lymphogranuloma venereum, and granuloma inguinale [2]

The "primary lesions' of the venereal diseases are all inflammatory reactions to inoculation with specific agents The lesions are essentially granulomas and depend mostly upon the isolation of the individual causative agent for their specific identification Wherever possible, this procedure is a *sine qua non* in the diagnosis of the early acute lesions The clinical appearance of the lesion is no criterion for the recognition of any specific disease entity It is only a 'clinical hunch" at best, even when that initial lesion is caused by a single entity When the initial lesion is caused by two or more concurrent infections, an exact clinical evaluation is hazardous and unreliable An analysis of a series of cases of chancroid[3] and another series of cases of lymphogranuloma venereum[4] showed that the majority of patients suffering from these venereal diseases have more than one venereal disease at the time of their examination Thus, any records based upon clinical criteria alone must necessarily possess a very large margin of error The insistence that any clinical criteria can be relied upon disregards the very painstaking and accepted work of Schaudinn and Hoffmann (the spirochete pallida, 1905), Ducrey (the Ducrey bacillus, 1892), Donovan (Donovan bodies, 1905),[5] and Neisser (the gonococcus, 1879) The characteristic pathologic findings of lymphogranuloma venereum have been described adequately [6]

How reliable are the methods of identification of the specific agents from primary lesions? The spirochete pallida may be demonstrated on darkfield examination from seronegative primary syphilitic lesions in 94 per cent of the cases [1] In some of the remaining 6 per cent, the diagnosis can be ascertained by gland puncture The Ducrey bacillus may be demonstrated on smear from the chancroidal lesion in 88 per cent of the cases by means of the Unna-Pappenheim stain [3] In the remaining 12 per cent of the cases, a therapeutic test using the sulfonamides will help to clarify the diagnosis Donovan bodies may be demonstrated on smear from acute lesions of granuloma inguinale in over 95 per cent of cases by means of Wright's stain [7] The gonococcus may be identified on smear and culture from any unusual lesion The demonstration of the virus bodies of lymphogranuloma venereum is still too difficult for routine laboratory procedure However, a characteristic histopathologic lesion may be seen in the excised lymph nodes in over 80 per cent of the cases [6]

Thus, before any confirmatory tests are indulged in, it is possible to arrive at a correct diagnosis in most of the cases When a primary lesion on the genitalia is observed, the following procedures are available and should be carried out first

1 For the spirocheta pallida, repeated darkfield examinations to exclude syphilis

2 For the gonococcus, repeated smears and cultures to exclude gonorrhea

3 For the Ducrey bacillus, smears stained by the Unna Pappenheim stain to rule out chancroid

4 For Donovan bodies, a smear stained by Wright's methods to rule out granuloma inguinale

5 For spirocheta pallida, and the identification of any micro organisms, or the aspiration for making Frei antigen, a "gland puncture "

When all of these methods are utilized and all are found negative, the following confirmatory tests should be added

1 A blood Wassermann reaction to exclude syphilis

2 Biopsies of the local lymph nodes to exclude lymphogranuloma venereum, acute lymphadenitis, tuberculosis, metastatic carcinoma, or blood dyscrasia

3 Biopsies of the local lesions to rule out carcinoma in particular

4 Aspiration of any pus present to make Frei antigen and to test it on known and control cases

5. The performance of the known intradermal reactions—the Frei test,[4] the Ducrey vaccine test,[3] and the granuloma inguinale intradermal reaction.[8]

Biopsies of the local lesions are not of great value in the differential diagnosis of the common venereal diseases. Until recently the description of the histopathology was actually that of granulation tissue resulting from secondary infection. At present, there is no clear-cut histologic differentiation of the primary lesions.

Comment

From the foregoing, it is important to give due emphasis to our essential differential diagnostic procedures which are at present available in the diagnosis of early-lesion of venereal diseases. It is likewise important to give each of these diagnostic methods its proper evaluation. When a single test presents inadequacies, a confirmatory test may be essential and sufficient to establish the correct diagnosis. Mixed infections are more common than is generally realized. Complicated lesions may be differentiated and analyzed when all our diagnostic methods described are diligently followed through. The clinical appearance of a lesion is the least important factor in the diagnosis of early lesions of the common venereal diseases.

RED CROSS EXPANDS WHOLE-BLOOD PROGRAM

In response to urgent requests from the Pacific battle area for more whole blood, the American Red Cross is extending the West Coast whole-blood project to include San Diego and Portland, it was announced on January 9 by Basil O'Connor, Red Cross National Chairman. At the same time, procurement of whole blood in San Francisco, Oakland, and Los Angeles is being stepped up.

Mr. O'Connor said that the San Diego and Portland centers will begin collecting whole blood as soon as arrangements can be completed. With this addition, all West Coast centers will be procuring whole blood as well as plasma.

He said further that the expansion had been authorized at the request of Vice-Admiral Ross T. McIntire, Surgeon General of the Navy, and was based upon urgent requests from the Pacific theater to increase whole-blood shipments without delay. Whole blood is used primarily in hospitals and aboard hospital ships to supplement the use of plasma in the front lines.

In addition to the Pacific whole-blood project, five Centers on the East Coast are procuring whole blood for Europe, Mr. O'Connor stated. These are Boston, New York, Brooklyn, Baltimore, and Washington. Type O whole blood procured by these Centers is flown daily to Europe by the Army Air Transport Command, while the whole blood procured on the West Coast is flown to the Pacific by the Naval Air Transport Service.

Besides the ten East and West Coast Centers engaged in procuring both whole blood and plasma, twenty other Centers procure blood for plasma. A total of approximately 100,000 donors a week is required to keep the armed forces fully supplied, Mr. O'Connor said.

"In the past," Mr. O'Connor stated, "appeals for blood donors have led to numerous requests that the Red Cross set up additional procurement facilities in other cities. Unfortunately, this is impractical, partly because Centers must be located near the processing laboratories and also because the present Centers and mobile units can provide all the blood required. It should be understood, therefore, that appeals for donors are directed only to persons living in or near Blood Donor Center cities. With their continued cooperation, there is no question that the Red Cross can keep the armed forces fully supplied."—*American Red Cross News Service Release, Jan. 9, 1945*

X-RAY SURVEYS SHOULD INCLUDE WHOLE COMMUNITY

Sound public-health practice demands that the method used in mass radiography for the control of tuberculosis be one which benefits the largest number of persons in industry or the community. When available funds are limited, it is of greater value to examine 100,000 persons with small films and miss a few minimal cases than to examine only one-tenth of that number at about the same cost, using large celluloid films and leaving 90,000 persons without benefit of any x-ray examination whatever. —*H. E. Hilleboe, M.D., and D. M. Gould, M.D., J.A.M.A., May 24, 1944*

ATTITUDES TOWARD SEX

HAROLD KELMAN, M D , New York City

THE purpose of this communication is to discuss some of the attitudes toward sex in our culture and the meaning of such attitudes Reference is made to various types of sexual activity in children and adults The difference in what is regarded by men and women as being sexually derived is described Some comments are made about the manifestations of symbolic sexual thinking in our waking and dream life

We will first discuss sex activity in children Many of us attempt to blind ourselves to the normal and abnormal manifestations of sexual curiosity in childhood It is something of an anomaly in our society that the natural curiosity of children is applauded in all directions except with respect to biologic facts A child is aware of its body before it has any real appreciation of self It is normal and natural for it, therefore, to explore all the bodily orifices and to stimulate any parts of its body for pleasure Yet the attitude of the majority of parents is such that the child's natural curiosity becomes inhibited and frustrated This consequently leads to the development of abnormal fears with resultant distortions of interest and activities in bowel, bladder, and genital functions

Masturbation occurs at some time and in some form in the normal development of all individuals Our attitudes of disapproval toward such activity are so drastic, however, that many adults have repressed the memory of such experiences This is particularly true with women, who tend to feel more guilty about masturbating than men because of the sexual attitudes still operative in our culture Normally, with the advent of adolescence and a growing interest in the opposite sex, the emphasis on masturbation lags and is supplanted by the natural desire for heterosexual relations Unfortunately, the mistaken notion still exists that masturbation is a particularly harmful practice Masturbatory activity is no more injurious than any other activity engaged in to excess What has significance for us primarily are the attitudes regarding this activity rather than the activity itself

Adolescence calls for drastic emotional adjustments in all children Female childen today are somewhat better prepared for the advent of menstruation Consequently they do not view it with the dread and horror that they formerly did An interesting expression of our cultural attitude toward menstruation is manifested by the frequency with which women refer to it as "the curse"—a deep-rooted remnant of the belief in original sin and the physical inferiority of women Today an increasingly larger number of women limit their activities less during the menses A widespread prejudice against sexual activity during menstruation still exists

Participation in sexuality during menses is quite common and practiced without physical or psychologic injury It might be added that in these times of war, when servicemen are home on leave for limited periods, it would be good mental hygiene to dissipate such unfounded prejudices which can have, and frequently do have, harmful emotional effects on both parties concerned

The duration and frequency of sexual activity are not only matters of individual preference, they are also strongly affected by cultural attitudes In some cultures, for example, sexual activity is encouraged in the young, whereas in our own, as we have seen, even self-exploratory activity in children is frowned upon

As to the duration of sexual life, we accept without basis that sexual activity necessarily wanes with advancing years Factually, many men and women in the fifties and even in the sixties enjoy frequent sexual intercourse with orgasm and considerable satisfaction

In all cultures, sexual activity may become perverse in its object or its aim Homosexuality may be said to exist, therefore, when a person of the same sex is taken as a love partner to function in an active or passive role or both Contrary to widespread belief, there are very few individuals in whom we can definitely say that there is a biologic basis for homosexuality Resorting to endocrine therapy as a first remedy before a thorough psychologic analysis robs the individual in question of a real opportunity to obtain mental health and also thwarts investigation of this problem Clinical experience has further proved that a number of homosexuals can be treated by psychologic methods

By sexual perversion we generally mean that the activity is distorted All the orifices of the body are used for entrance and contact In addition, the sexual activity may be limited to one aspect of the whole sequence of acts leading to the consummation of heterosexual or homosexual activity Most of these activities may be considered as part of normal sexual activity as long as they are not indulged in as an end in themselves or for the satisfaction of humiliating, or other neurotic tendencies on the part of either or both

Lecturer American Institute for Psychoanalysis

partners. We would then have what we consider pathologic deviations in the sex act.

The frequency of sexual activity, whether marital, premarital, or extramarital, is a question of the desires of the two persons concerned in a mutually cooperative activity for the purpose of pleasure and procreation. The satisfactory achievement of this mutual cooperation is difficult to obtain in our culture because the feeling that the enjoyment of sex is sinful is still so deeply ingrained in many allegedly emancipated members of our society.

Likewise in our society, the acceptance of the double standard for men and not women is culturally determined. A man is supposed to "sow his wild oats" in premarital relationships. This attitude, however, is rapidly changing with the increase of career women. This change has been hastened by the war through the departure of large numbers of men. Sexual freedom for women has been further aided by the dissemination of sex hygiene information in the younger age groups and through the greater availability of contraceptive aids which has lowered the frequency of venereal diseases and illegal operations.

The need for extramarital sexual relationships is not an expression of the lack of sexual satisfaction with the partner, but rather an evidence of a deeper disturbance in the whole interpersonal relationship manifesting itself in a disturbance of the sex act. Thus, a husband or wife may rationalize their right to indulge in extramarital affairs because their marital partner is sexually unresponsive. Upon closer examination, it often develops that the whole fabric of their relationship is emotionally warped and devoid of pleasure.

Any discussion of extramarital relationships usually turns, sooner or later, to the topic of frigidity in women. Here we have a classic example of putting the cart before the horse. Our cultural attitudes specifically foster frigidity in women and then insist that women are more difficult to arouse sexually than men. This is a biologic fallacy. Well-adjusted women are just as eager for sexual activity as are well-adjusted men; they are aroused just as easily and obtain equally as much pleasure from the sexual act.

There are, of course, degrees of pleasure in sex as well as in all other human activities. Normally pleasure is obtained from all aspects of sexual activity and, depending upon mutual consent, may be of limited extent, or continue on to complete orgasm. The romanticized version of sex is a state in which the individual is carried away and there is a loss of self. It is something literally "out of this world," the ultimate in ecstatic bliss. Actually, it is really nothing of the kind. What we have here is the use of sex as a neurotic escape mechanism, much as may be observed in individuals who use hypnotics, alcohol, and drugs for the same purpose. Factually, a natural orgasm is a heightened state of pleasure with conscious awareness, as a culmination of heterosexual activity by two mutually cooperative individuals. The romanticized notion of loss of self, therefore, actually prevents the individuals from full, conscious enjoyment of a highly pleasurable act. Unfortunately, in our culture, sex and love are synonymous terms. Sex does not equal love, nor does love equal sex. Love can be defined as a state of pleasurable mutuality which when present between two persons of the opposite sex may have as one of its aspects pleasurable sexual activity.

From what has been noted previously, it is not surprising that there are cultural determinants for the use of "man" and "woman." We use the word "man" in an anatomic sense, as a qualifying adjective and as an all-inclusive symbol to denote the human race. The word "woman," on the other hand, while it has anatomic and qualitative meanings, is never used in our culture to denote the human race. It might be argued that "man" is merely a generic term, which for convenience continues to be used and which has long since lost its essentially "masculine" connotation. But how, then, explain that the qualities "masculine" and "feminine" also have fallacious connotations in our culture?

"Womanly," for example, or "feminine" is synonymous with softness and warmth, while "manly" and "masculine" denote strength and virility. These categoric attributes are merely projections, however, of our cultural attitudes. They are not biologic characteristics of men or women. They are rather accepted and culturally predetermined characteristics of what we believe to be the difference between the sexes. Actually, the qualities of warmth and strength are innate to all human beings.

In an attempt to sustain the contention that women are basically different from men, or vice versa, the point is frequently made that, after all, only women can bear children. But, for that matter, only men can impregnate women. Then again, the position is often taken that women can have many children from one or many men, with the implication that this makes them radically different from men. But those who argue that point frequently fail to mention the fact that one man can be the father to many children by one woman or many women. This is merely by way of illustrating that the use of an anatomic argument to prove a psychologic point is both an evidence of unclear thinking and an attempt to evade the real issue. What we are

interested in is not the sexual anatomic differences per se, but the psychologic attitudes toward those sexual anatomic differences, as determined by our particular cultural patterns

Men who are emotionally insecure often attempt to obtain a feeling of security by assuming a dominating position toward women This is as true in our contemporary society as it was in the Victorian era But in the last few years, social changes have been so rapid that these men feel threatened by the increasing emancipation and freedom which women have obtained Such men feel that the way things are going, the time is not far off when women will become uncontrollable and completely out of hand Yet at the same time these men, who assume the role of the benevolent stronger male caring for the helpless and weaker-minded female, complain bitterly but secretly enjoy the fact that women are "different" and not endowed with the sense of justice, comradery, stability, and clear-headedness which they feel are peculiarly male characteristics The point that this type of man overlooks is that a woman functioning as a person in a real, cooperative, interpersonal relationship would not be such a problem to him and would not have to exact or have thrust upon her the alleged special privileges, prerogatives, and deferences shown to her in our culture

Although it may appear that men are mainly responsible for this situation actually women unconsciously, and often consciously, nurture and invite just those attitudes They feel that they are gaining by these special privileges but at the same time contradictorily want to be treated 'just like men" Clearly they would be better off without these special prerogatives or being treated "just like men" if they devoted their energies to becoming their own selves

Our social attitudes toward sex have also created an extensive vulgar male vocabulary in which sexual activity is referred to in violent and humiliating terms This is a direct reflection of our deeply ingrained conception of sex as a violent and humiliating assault on a woman by a man in which she is harmed and is the unwilling partner Our romantic literature fosters this general conception and, as a result, many men and women have to recreate this neurotic setting before they can obtain sexual "satisfaction" Usually, however, women do not express themselves sexually in vulgar terms In accordance with the rule of the romantic game, all references to the sexual act must be indirect A man may be referred to as having a nice "physique' and being "clean-limbed," but any direct reference to the male genital region is strictly taboo

Sex can be used for the same neurotic purpose by both men and women And what holds true for sex holds for any thought, feeling, or act which is shared by two individuals What concerns us primarily is the meaning which that thought feeling, or act may have for the individual in relationship to himself and to those with whom he lives

Instead of the sexual act being indulged in for pleasure, it is more often used for the purposes of humiliation hostility, and disparagement as well as for the purpose of power and prestige Men frequently use it to gain approval, to inflate their sense of importance, and to bolster their self-doubted potency Many women use sex as a lure to ensnare their men as well as to obtain gifts and admiration as an object of sexual desire Inasmuch as all of these are perverted uses of the original function of the sexual act, they inevitably leave the participants with a feeling of dissatisfaction

One of the most common symptoms of sexual maladjustment in male patients is premature ejaculation Modern psychoanalytic research has revealed that one basic cause of the difficulty these organically sound men have often lies in their hostile attitude toward women [1] They do not want to give women any sexual satisfaction and ejaculate prematurely out of unconscious spite It is a form of protection, a means of preventing them from coming close to a woman for fear that she might sense their hostility and retaliate in kind In a broader sense, premature ejaculation may also be a symptom of a generally antisocial attitude Some men are afraid of any close human contact because it might prove a threat to their false notions of independence and misogynistic self-sufficiency Frigidity in women may also have a similar connotation, or it may be that they must deny having had any pleasure Admission of such pleasure might mean to them the existence of an obligation which they cannot or do not want to repay

The excessive emphasis on sex in our culture is manifested in our dream language Many dreams which seem to be purely sexual in nature are actually only superficially concerned with sex [2] Modern psychoanalysis has revealed many significant social attitudes in the character of the dreamer which have little to do with sex, per se

For example, a young man dreams that he lies on a couch He has a long penis which reaches from himself to a woman who stands some distance off At first glance, this dream seems to be concerned with the problem of potency The patient's history reveals that it has quite a different meaning Factually he has no sexual problem All his life this patient has insisted on lying back while women were at his beck and call, assumed all responsibility, and were the active partners in the relationship In other words,

women were relegated to a safe distance, near enough to be enjoyed in carefree comfort, but sufficiently far away to make it impossible for them to affect him personally or to encroach on his privacy. His dream, then, reveals his abhorrence of closeness in a relationship and his distaste for actively assuming any kind of direct responsibility, as well as a desire to dominate by remote control.

Again, a woman dreams she is nude in bed with a naked man on either side of her, an apparent confession of extreme sexual lust. But in real life, this woman always managed to have two men on her string as a protection, because she wanted neither and feared both. She played one against the other for what she could get out of them and so prevented either from coming close to her and making demands. The disturbance in her sexual relationship as expressed in her dream was merely a manifestation of her disturbed interpersonal relationships in general. Actually, this woman was not only frigid but felt nauseated at the idea of a man kissing her; she never had any sexual experience or anything remotely approximating it.

It is fairly common for a female patient to "fall in love" with her analyst. She may overtly or covertly suggest a sexual relationship, and she may even believe that her desires are quite sincere and legitimate. Yet, on examination, we commonly find that the proposed liaison has ulterior motives. The patient either feels that she could dominate the situation if she could make the analyst respond to her advances, or else it might be a means of breaking off the analytic relationship, or a desire to compromise the analyst professionally. If this could be accomplished, everything unpleasant or unacceptable which the analyst had said could, she feels, be invalidated on the grounds of lack of professional dignity or ability.
